Simplifying Choices in Defined Contribution Retirement  
Plan Design: A Case Study

## The CFS Working Paper Series

presents ongoing research on selected topics in the fields of money, banking and finance. The papers are circulated to encourage discussion and comment. Any opinions expressed in CFS Working Papers are those of the author(s) and not of the CFS.

The Center for Financial Studies, located in Goethe University Frankfurt's House of Finance, conducts independent and internationally oriented research in important areas of Finance. It serves as a forum for dialogue between academia, policy-making institutions and the financial industry. It offers a platform for top-level fundamental research as well as applied research relevant for the financial sector in Europe. CFS is funded by the non-profit-organization Gesellschaft für Kapitalmarktforschung e.V. (GfK). Established in 1967 and closely affiliated with the University of Frankfurt, it provides a strong link between the financial community and academia. GfK members comprise major players in Germany's financial industry. The funding institutions do not give prior review to CFS publications, nor do they necessarily share the views expressed therein.

# Simplifying Choices in Defined Contribution Retirement Plan Design: A Case Study\*

Donald B. Keim and Olivia S. Mitchell

The growth and popularity of defined contribution pensions, along with the government's increasing attention to retirement plan costs and investment choices provided, make it important to understand how people select their retirement plan investments. This paper shows how employees in a large firm altered their fund allocations when the employer streamlined its pension fund menu and deleted nearly half of the offered funds. Using administrative data, we examine the changes in plan participant investment choices that resulted from the streamlining and how these changes might affect participants' eventual retirement wellbeing. We show that streamlined participants' new allocations exhibited significantly lower within-fund turnover rates and expense ratios, and we estimate this could lead to aggregate savings for these participants over a 20-year period of \$20.2M, or in excess of \$9,400 per participant. Moreover, after the reform, streamlined participants' portfolios held significantly less equity and exhibited significantly lower risks by way of reduced exposures to most systematic risk factors, compared to their non-streamlined counterparts.

## Simplifying Choices in Defined Contribution Retirement Plan Design: A Case Study

Working Americans have increasingly relied on employment-based defined contribution (DC) retirement plans as the more traditional defined benefit (DB) pensions have declined over the past 50 years.<sup>1</sup> A distinguishing feature of DC plans in the U.S. is that participants must decide how much to contribute and where to invest their retirement assets, instead of holding the employer responsible for plan investments. Employees make these decisions within the menu of investment options offered by plan sponsors, and employers often automatically enroll participants into ‘default’ investments if people do not elect an option.<sup>2</sup> Recent research in social psychology has argued that too many choices may create confusion, resulting in poorly-informed consumer decisions (e.g., Iyengar and Lepper, 2000).

Relatively little is known about how changing the fund lineup can shape employee investment choices in DC plans.<sup>3</sup> We seek to fill this gap using administrative data provided by a plan sponsor. The information enables us to examine how participants contributed to a menu of funds and what happened to their fund allocations, along with the costs and risks of the resulting portfolios, as a result of a firm-wide DC plan streamlining effort. In all, the plan menu in the firm was reduced considerably, with almost half of the funds deleted from the lineup. This streamlining

---

<sup>1</sup> The US Department of Labor (2014) reports that in 1975, 74% of all participants in private sector plans were covered by DB plans; by 2012, only 6% of participants were in DB pensions.

<sup>2</sup> There is a separate strand of literature that focuses on the adequacy of the list of choices offered to DC participants; examples include Angus, Brown, Smith, and Smith (2007), Choi, Laibson, Madrian, and Metrick (2002), Dvorak (2015), and Elton, Gruber, and Blake (2006). We are interested here in the decisions made by participants in response to changes in the list of choices.

<sup>3</sup> Various researchers have explored other aspects of plan design and participant behavior, including participation, contribution rates, and investment of employer stock; see for instance Choi, Laibson, and Madrian (2004), Mitchell and Utkus (2006), and Huberman, Iyengar, and Jiang (2007). Additionally, prior analyses describe how participants who are automatically enrolled end up allocating their DC savings (Madrian and Shea, 2001).

process was intended to simplify the fund menu, but it is important to note that the average characteristics of the menu of offered funds (e.g., expense ratio, within-fund turnover, systematic and idiosyncratic risk) were the same before and after the streamlining.

We examine plan participants' investment choices prior to and after the streamlining event and evaluate what happened to participant fund allocations, risk exposure, and costs as a result of the reform. First, we explore what types of individuals held the deleted funds and how (if at all) they differed from other participants. Based on participant holdings on June 30, 2012, just before the changes were announced in July 2012, we define the holders of these deleted funds as the *streamlined* participants, and their counterparts as the *non-streamlined* participants. Second, we evaluate how streamlined participants responded to the changes, and how they reallocated their retirement assets after the reform. Third, we show how the streamlining process affected participants' portfolio turnover, risk, and expenses.

We find that participants subject to the streamlining proved to be older, more likely to be male, and higher-income; they also held higher balances in riskier funds and lower balances in safer balanced/target date funds. Participants holding the deleted funds either (a) reallocated their money to funds kept in the lineup in advance of the deadline to maintain a similar pre- and post-streamlining allocation, or (b) were defaulted into Target Date Funds (TDFs) resulting in an allocation containing, on average, safer assets. Only 9% of the streamlined participants (N=211) elected the new brokerage window (taking only 0.4% of their assets). Post-streamlining, the streamlined participants adjusted their portfolio holdings, ending up with fewer funds, significantly lower within-fund turnover rates, and lower expense ratios. Based on reasonable assumptions, these portfolio adjustments could lead to potential accumulated savings for these participants over a 20-year period of \$20.2M, or more than \$9,400 per participant. Also, after the reform and relative

to the non-streamlined participants, streamlined participants' portfolios generally exhibited lower diversifiable/idiosyncratic risk and less exposure to systematic/non-diversifiable risk factors.

In what follows, we first offer a brief literature review, followed by a discussion of our data and descriptive statistics. We then use multivariate regression models to estimate differences in the changes in portfolio characteristics and risks for participants affected by the streamlining compared to those who were not, controlling for several participant attributes. We conclude with thoughts on how a streamlining intervention such as this might shape employees' eventual retirement wellbeing.

## **1. Related Prior Literature**

Recent research in social psychology has argued that too many choices can create confusion and distraction, resulting in poorly-informed consumer decisions (e.g., Iyengar and Lepper, 2000). In the context of DC fund menus, Iyengar, Huberman, and Jiang (2004) asked whether such "choice overload" affected participation decisions in the 401(k) environment. They used a 2001 cross-section of participant-level data for 649 DC plans managed by the Vanguard Group to determine whether *participation rates* were lower in plans when more funds were on the menu. Controlling for a variety of employee attributes (e.g., compensation, gender, age) and plan attributes (e.g., number of employees, whether company stock was offered, number of funds offered), they found that for every 10 additional funds on a menu participation rates dropped two percent. While most of the plans examined had 10-30 options, participation rates were actually highest for those with 10 or fewer options.

Researchers have also asked whether plan design and complexity affect how participants *allocate across funds* on the plan menu (e.g., stock vs. bond funds) and the *number of funds* in

which they invest. Financial economics suggests that participants in a pension plan should rationally focus on their own portfolios' risk-return profiles independent of the number of funds in their pension plan menu. Yet Benartzi and Thaler (2001) suggested that plan participants actually followed a naïve diversification approach, investing  $1/n$  of their assets in each of the  $n$  funds made available in the menu. Similarly, suboptimal investment decisions were reported by Tang, Mitchell, Mottola, and Utkus (2010) who showed that even when plan sponsors offered a sufficiently diversified (efficient) menu of funds, participants regularly selected inadequately diversified portfolios given their selected level of risk.

In a related vein, Brown, Liang, and Weisbenner (2007) employed SEC 11-k filings on 891 401(k) plans from 1991-2000 to show that the mix and number of stock and bond funds on a plan menu affect participant investment choices. The panel nature of their dataset (*plan-level* data for 10 years) permitted the authors to use firm-level fixed-effect regressions. They found that the relative mix of investment options on a 401(k) menu (i.e., the number of equity funds, the number of bond funds, etc., as a percentage of the total number of options offered) is an important predictor of how participants allocate contributions across these asset classes. Put differently, if stock funds make up the largest share of a plan's offerings, participants will allocate the largest share of their contributions to stock funds.

In a more recent study, Morrin, Inman, Broniarczyk, Nenkov, and Reuter (2012) examined how employees covered by the Oregon University System DC plan altered their selection of funds when their plan menu was expanded from 10 to 19 fund choices in July 2007. Both before and after the expansion (the authors' *participant-level* data cover Feb 1998 to Mar 2010), the default was a money market fund. When the smaller menu was offered, 21% defaulted to the money fund, while with the larger menu, 34% defaulted. Accordingly, the authors concluded that offering more

funds (p 548) “may be overwhelming for many investors.” Of those who did make an election, participants selected on average 37% (3.7 funds) of the funds from the 10-fund menu, and 27% (5.3) from the 19-fund menu. While those results did not support the  $1/n$  heuristic, they were consistent with perhaps a weaker form of the heuristic whereby increasing the number of offered funds led participants to hold more funds. Moreover, the authors (p. 547) concluded that while it may be sensible for plan sponsors to offer a sufficient variety of choices, there is a need to “clearly categorize the options to help the [participants] perceive the set of offerings at a higher, more abstract level. Partitioning the funds may enhance asset class diversification while not reducing (and actually increasing) the total number of funds invested in. Subjectively grouping funds by asset class is more likely to assist novice investors than expert investors in their financial decision making.”

Finally, Huberman and Jiang (2006), using the same *participant-level* 2001 data from 649 DC plans in Iyengar, Huberman and Jiang (2004), found that (p. 763) “the number of funds used [by participants], typically between three and four, is not sensitive to the number of funds offered by the plans, which ranges from 4 to 59.” They also report that (p. 764) “there is little relation between the proportion of contributions that participants allocate to equity funds (equity allocation) and the proportion of equity funds that their plans offer (equity exposure).” They also report that (p 765) “Once plans offer an abundance of choices (more than 10 funds), there is no correlation between equity allocation and exposure.” Thus, in contrast to the conclusions in the three studies mentioned above, Huberman and Jiang conclude from their *participant-level* analysis that participants’ decisions on how to allocate and in how many funds does not appear to be related to the number or mix of plan offerings. However, at the *plan level* they discovered that (p. 776) “the more funds offered, the more funds used.” They report that when 10 (30) funds were offered

in a plan, 75% of the dollars invested in the plan were allocated across 5 (11) funds, a finding that is more consistent with the other papers.

Despite the lack of a consensus, it is reasonable to conclude that prior research confirms that the number and mix of DC fund options can influence investment patterns in retirement accounts. Nevertheless, there is little to no evidence on how differences in the *fund options* affect costs and risks of participant portfolios.<sup>4</sup> Moreover, no study has yet examined how participants react to a rather substantial *reduction* of retirement plan investment choices. In what follows, we explore these issues with a unique new administrative dataset that permits us to follow investor behavior before and after a substantial streamlining in the fund menu and document the effects of the reform on the costs and risks associated with participants' portfolios.

## 2. The Setting

The employer we study is a large US nonprofit institution. Like its peers, it has long offered a DC structure to cater to participants' retirement saving needs on a pre-tax basis. Prior to 2013, the plan included almost 90 mutual funds in the investment menu, ranging from equity to target date to bond index funds, as well as REIT, commodity, and other sector funds. Cognizant of the growing literature on choice overload (see references in section 1), the firm's investment committee in 2011 determined that a shorter list of offered funds would be easier to administer, explain, and rationalize, compared to the prior menu.

To this end, the committee streamlined the plan menu and arranged the remaining funds into four tiers designed to accommodate participants with differing levels of investment

---

<sup>4</sup> Beshears, Choi, Laibson, and Madrian (2013) evaluated how a simple saving rate and asset allocation protocol in a DC plan affects the probability of participating and contribution rates conditional on participation; they did not, however, look at asset allocation patterns.

sophistication. Participants who had invested in the funds that would be eliminated from the menu would be allowed to reallocate their assets and contributions to any other fund in the menu, and anyone who did not move his assets out of the funds to be deleted would have his assets automatically transferred to an age-appropriate Target Date Fund (TDF).<sup>5</sup> Alternatively, participants who elected to do so could move their assets to a new self-directed brokerage account within the plan which would give them access to not only the closed funds, but also thousands of other mutual funds.

The result was the elimination of 39 funds from the initial lineup, based on the funds' expense ratios, similarity of return and risk characteristics with retained funds, and the number of participants and aggregate amount invested in each fund.<sup>6</sup> Remaining funds were allocated across the new four-tier structure, where each successive tier would afford participants additional choice. Tier 1, selected as the default tier for participants not actively electing an investment mix, included 13 low-cost Target Date Funds. Additional tiers offered increasing flexibility of choice for participants seeking to make more customized and sophisticated allocations. Tier 2 included four indexed funds: Money Market, U.S. Diversified Stocks, U.S. Bonds, and Diversified International Stocks. Tier 3 included 32 funds arranged into separate "risk" categories illustrated in more detail in Table 1. The range of categories included: small/mid/large-cap and value/growth stock funds;

---

<sup>5</sup> This was defined as the TDF with the target date closest to the year the participant would attain age 65. Under the Pension Protection Act of 2006, the US Department of Labor permits TDFs as QDIAs (qualified default investment alternatives) that can be used for participants who do not elect their own investment mix.

<sup>6</sup> In results not reported here (available on request) we find that the average characteristics of the menu of offered funds (e.g., expense ratios, within-fund turnover rates, and systematic and idiosyncratic risk) were not significantly different before versus after the streamlining. The average return correlation of the deleted funds with the retained funds, measured over the January 2006 to Dec 2010 period, was: 0.960 for the international stock funds; 0.965 for the domestic stock funds; and 0.947 for the domestic balanced funds.

small/mid/large-cap international stock funds; short/intermediate/long-maturity Treasury and corporate bond funds; balanced funds; and a passive equity REIT fund to provide access to the real estate asset class. Tier 4 constituted the brokerage account. It is evident from Table 1 that much redundancy in fund offerings, and associated potential for confusion, was eliminated from the menu as a result of the streamlining.

*[Table 1 here]*

The plan sponsor announced its streamlined fund lineup in July 2012, with an implementation date of mid-October 2012. In addition to a newsletter sent to all participants, the employer created a custom website, broadcasted online webinars, sent targeted emails, held participant meetings, and sent hard copy mail to explain the changes.

### **3. Data and Descriptive Statistics**

To analyze the change in behavior post- versus pre-streamlining, we obtained access to information on the retirement plan account balances and periodic contributions of all the (identity-censored) participants. Our administrative dataset included information on contributions, balances, and asset allocation prior to the streamlining, defined in our analysis below as end-June 2012, and after the change, defined as end-December 2012. To this file we appended information from public sources (via ticker and CUSIP numbers) for each fund's equity fraction and style (bond, balanced, stock, etc.), as well as monthly return histories. The fund administrator also provided individual demographic information on participants' age, sex, education (highest degree from graduate school

versus less than graduate school), and, from external sources, imputed household income (assigned according to the participant's zip codes, where low <\$50K, middle \$50-100K, and high >\$100K).<sup>7</sup>

Using the participant balance and contribution data, we identify participants whose holdings were directly affected by the streamlining. Specifically, we separate participants into a Streamlined group – those participants who held funds at end-April 2012 that were subsequently deleted due to streamlining – and a Non-Streamlined group. Additionally, we separate the streamlined participants into two subgroups: “Plan-Defaulted & Streamlined” are the streamlined participants who took no action after the announced streamlining and were defaulted by the Plan into an age-appropriate TDF at the October deadline; and “Not-Plan-Defaulted & Streamlined” are the streamlined participants who exchanged out of the deleted funds prior to the October deadline.

To illustrate how the reform worked, we begin by reviewing descriptive statistics on the balances in the retained and deleted funds by risk category, and we also compare key attributes of participants and their retirement plan investments as of end-June 2012 (our baseline). Table 2 reports aggregate balances held in retained and deleted funds by risk category, where of the almost \$1 billion invested at end-June 2012, most of the assets (80%) were held in retained funds. Overall, 20% of the total assets were in funds that were subsequently deleted; of those, about 60% had been in equity (stock, balanced, or international) funds, 24% in alternatives/sector funds, and 14% in bond funds (with the remainder in money market funds).

*[Table 2 here]*

---

<sup>7</sup> These were derived from data supplied to the plan administrator from IXI Corporation and derived from zip+4 Census tract information. (See <http://www.ixicorp.com/products-and-services/customer-targeting-and-scoring/wealthcomplete/>)

In Table 3 we report aggregate dollar balances, the number of total participants, and the number of funds held by all plan participants at end-June 2012 (rightmost column), along with the same information for the Streamlined participants (who owned at least one deleted fund) and the non-streamlined participants (who owned no deleted funds). The number of participants in each group was roughly similar (2,238 versus 2,371), but the Streamlined group had accumulated almost 60% more in assets (\$603.8 versus \$380.0 million), contributed 30% more on a monthly basis (\$1802 versus \$1356 per participant), and held more funds overall (87 in total versus 47). On average, about one-third of the contributions of the Streamlined participants were in funds that were subsequently deleted and two-thirds in retained funds.

*[Table 3 here]*

A comparison of characteristics for Streamlined versus Non-Streamlined active participants appears in Table 4. The Streamlined participants were significantly older, more likely to be male, lived in higher-income households, and were more likely to have earned graduate-level degrees. They also owned three times as many funds (an average of 6.8 versus 2.1) compared to the non-streamlined participants. Regarding asset allocations, Table 5 indicates that the Streamlined participants were more likely to contribute directly to stock funds (sector, domestic and international), while the Non-Streamlined participants were more likely to obtain equity exposure (indirectly and in more conservative amounts) via significantly larger allocations to target date funds.<sup>8</sup> As a result, on average, the Streamlined participants held portfolios containing more equity exposure. One might speculate that these results suggest that Streamlined participants made more sophisticated choices than the younger less-affluent Non-Streamlined participants

---

<sup>8</sup> Given the age profile of the non-streamlined sample, the average equity share of their investment in TDFs was just under 80%.

regarding how to allocate their retirement assets across the various investment options provided by the plan. Yet the fact that most of the Streamlined participants did not open brokerage accounts after the streamlining (see discussion below) in an effort to reproduce these allocations suggests otherwise.

*[Tables 4 and 5 here]*

#### **4. Changes in Portfolio Allocations: A First Look**

Table 6 reports how participants changed their retirement plan portfolios after the streamlining went into effect. In particular, we compare the allocation of retirement plan assets at two time points: prior to (as of end-June 2012), and after streamlining (as of end-December 2012). Overall, Non-Streamlined participants kept contributions to their retirement accounts virtually unchanged (column 3). Because these participants were not directly affected by the elimination of funds from the lineup, their persistence in the surviving funds refutes the idea that the reorganization and tiering of the surviving funds might have affected all participants' behavior.<sup>9</sup>

*[Table 6 here]*

By contrast, streamlining produced statistically significant and economically meaningful changes to allocations made by streamlined participants. To more clearly assess the allocation adjustment process, we separate this group into two sub-samples: (a) those Streamlined participants who did *not* take advantage of the window between the announcement in July and the deadline for action on October 19 and hence were defaulted by the Plan into age-appropriate target

---

<sup>9</sup> Although contributions by non-streamlined participants did increase for stock funds and decrease for "other" funds, the changes were economically tiny (0.4% and 0.1% respectively). In results not reported here, we also find that fund allocations by non-streamlined participants did not change significantly by the end of either 2012 or 2013, in terms of both contributions *and* balances.

date funds (Plan-Defaulted & Streamlined); and (b) those Streamlined participants who exchanged out of the deleted funds during the July-October 19 window (Not-Plan-Defaulted & Streamlined). The results for both streamlined groups are reported in the first two columns in Table 6. Both types of Streamlined participants significantly reduced allocations to stock, sector, and international funds and they shifted contributions mainly to TDFs. The changes were more pronounced, however, for the Plan-Defaulted members of the Streamlined sample: their allocations to stock, sector, international, balanced and bond funds fell significantly – by a combined 35.6% reduction in contributions, and their allocations to TDFs rose by 35.3%. By contrast, the Not-Plan-Defaulted Streamlined participants significantly decreased allocations to stock, sector and international funds (a combined 17.8% reduction) and significantly increased contributions to TDFs by 13.8%. The Not-Plan-Defaulted group also re-allocated a statistically significant 2% of its contributions to the new brokerage account.<sup>10</sup> Although we cannot see the transactions in these brokerage accounts, we might surmise that this shift in contributions reflects efforts by the Not-Plan-Defaulted group to continue investing in funds now eliminated from the Plan’s menu.<sup>11</sup>

---

<sup>10</sup> The amount re-allocated to brokerage accounts, \$2.7M, represents a small portion of the plan’s aggregate assets and few participants, only 9% of those holding deleted funds prior to the change, subsequently opened a brokerage account following the change. This may be because, at the time the brokerage accounts were announced, restrictions were imposed on the number of exchanges permitted in and out of certain funds each year. Also participants were informed that holdings in the brokerage account would incur special redemption fees of 1% (minimum \$50, maximum \$250) for no-transaction-fee funds; for transaction-fee funds, the participant would be charged \$20 per transaction. These fees were waived prior to the actual change. In both cases the minimum investment was \$1,000. Additional loads would depend on the share classes elected by each participant. This lack of participation in brokerage accounts reported here is consistent with broader evidence for DC plans reported in Vanguard (2015).

<sup>11</sup> This reallocation by both streamlined groups is expected given they were the participants holding the deleted funds. But it is interesting to note that the Streamlined participants were also the more active traders – in terms of number of fund exchanges – during the year prior to the announcement of the streamlining. During the period July 2011 to June 2012, the Not-Plan-Defaulted & Streamlined (Plan-Defaulted & streamlined) participants averaged 2.39 (1.9) fund exchanges per month, compared to 0.9 exchanges on average for the Not-Streamlined participants.

Table 7 helps us examine whether the pre- versus post-streamlining re-allocations were different for high versus low household income participants.<sup>12</sup> In the Non-Streamlined group there is little evidence of differences by income for pre- versus post-streamlining re-allocations; one exception is that low-income members of the Non-Streamlined group were more likely to shift allocations out of bond funds into the other available funds, although the magnitudes are very small (less than 1%). Within the Streamlined group, significant differences in re-allocations between high and low-income participants are mainly in the Plan-Defaulted sub-group. The most interesting finding, both statistically and economically, is that the overall re-allocations *into* TDFs seen in Table 6 prove to be 10% larger, and the re-allocations *out of* stock funds 7.6% larger, for the low-income members of the Plan-Defaulted group.<sup>13</sup> In other words, the streamlining reform had a larger impact on low-income savers, making their portfolios better balanced and less risky than before.

*[Table 7 here]*

## **5. Changes in Participant Portfolio Characteristics and Risks: Multivariate Analysis**

Next we use multivariate regression analyses to analyze in more detail how the reform shaped changes in the portfolio characteristics and risks of Streamlined and Non-Streamlined participants. To measure these differences, we again separate the Streamlined from the non-

---

<sup>12</sup> Recall, from section 3, that the low income group had household income of <\$50K; the middle group \$50-100K; and the high income group >\$100K.

<sup>13</sup> Before the streamlining (end-June 2012), the low-income members of the Plan-Defaulted Streamlined group had a higher contribution allocation (13.74%) to TDFs than the high-income members (9.06%). After the streamlining (end-Dec 2012), TDF contribution allocations increased substantially for both income groups, but the low-income group increased by more (to 55.36%) than did the high-income group (to 39.87%). These reallocations, both low income relative to high income, and December 2012 relative to June 2012, occurred in October 2012 when the streamlining was implemented.

Streamlined participants, and we further identify the two sub-groups of Streamlined participants with zero-one indicator variables, the *Plan-Defaulted-Streamlined* and the *Not-Plan-Defaulted-Streamlined*. Our analysis also controls for various participant attributes including age and age-squared (to test for possible nonlinear effects); male or female; educational level (graduate degree or not); and high versus low household income. We estimate the change in portfolio characteristics over two intervals: end-June 2012 to end-December 2012 (the same time period analyzed in Tables 6 and 7); and also end-June 2012 to end-December 2013 (a longer interval that allows more time for participants to adjust their portfolio allocations post-streamlining).

### *5.1 Changes in Portfolio Characteristics*

Table 8 compares the effects of the reform on participant portfolio turnover rates, expense ratios, number of funds held, and percentage allocation to stocks, in portfolios held by Streamlined versus Non-Streamlined participants. Panel A (B) reports model estimates for the shorter (longer) post-streamlining period.

*[Table 8 here]*

Over the shorter interval (Panel 8A), we find that, relative to Non-Streamlined participants, the Streamlined participants – both the Plan-Defaulted and those that were not defaulted – experienced significantly greater reductions in portfolio turnover, larger reductions in expense ratios, and a larger decline in the number of funds held. Moreover, these reductions were generally larger for the subset of Streamlined participants that were Not-Plan-Defaulted. For example, the reduction in the expense ratio was 6.0 (3.1) bps larger for the Not-Plan-Defaulted (Plan-Defaulted) Streamlined participants than for Non-Streamlined, and the difference of 2.9 bps is significant at the 0.01 level. This last result might be partly due to our inability to observe brokerage window transactions in which these Not-Plan-Defaulted participants might have replicated their prior fund

allocations and associated higher expense ratios. That said, recall that very few Not-Plan-Defaulted participants opened brokerage accounts; and virtually none of the Plan-Defaulted participants opened brokerage accounts.

In contrast to the findings for the other characteristics in Table 8A, the changes in the percentage of the portfolio allocated to stocks over the shorter interval were markedly different for the Not-Plan-Defaulted and the Plan-Defaulted streamlined subsamples relative to their non-streamlined counterparts. Specifically, the Plan-Defaulted Streamlined participants significantly *increased* their stock allocations by 1.3% by the end of December 2012, while the Not-Plan-Defaulted Streamlined group experienced a statistically and economically significant 4.8% *reduction* in stock allocation as a result of the streamlining. This difference of 6.1% is statistically significant at the 0.01 level, and it is consistent with Table 6 where we found: (a) a significant reduction in stock and sector fund allocations by the Not-Plan-Defaulted Streamlined participants; and (b) a significant increased allocation by the Plan-Defaulted Streamlined participants to TDFs which contain a much higher percentage of stocks<sup>14</sup> than the more conservative bond and balanced funds which they dropped, post- streamlining.

We also find that the reductions in stock allocations and number of funds held were greater for men than for women, consistent with Barber and Odean's (2001) finding for discount brokerage accounts that individual male investors trade stocks more aggressively than do female investors.

The message of Panel 8B is simple: the changes in portfolio characteristics for the Streamlined participants caused by the reform that were evident over the shorter interval in Panel A largely persisted over the entire 2013 calendar year. That is, their desired portfolio reallocations

---

<sup>14</sup> Sixty percent of the Plan-Defaulted streamlined group was under the age of 60. The average equity percent in the TDFs for this age range is about 86%.

were quickly established in response to the streamlining announcement, and those new allocations were left intact over the longer term. The one exception is that, during 2013, the Not-Plan-Defaulted Streamlined participants reversed the initial reduction in their stock market exposure (relative to the Non-Streamlined participants), so that by the end of 2013, their stock exposure was not significantly different than beforehand.<sup>15</sup> Otherwise, the initial effects of the reform (e.g., lower turnover and expense ratios) were not undone by Streamlined participant transactions over the subsequent twelve months.

Not only are these effects statistically significant: they are also economically important. That is, the (unconditional) average reduction in the annual expense ratio for the entire Streamlined group was 4.0bp (=27.9bp – 23.9bp), or a \$0.242M annual cost savings (based on the pre-streamlining balance for the Streamlined group of \$603.8M at end-June 2012). Since the average age of the Streamlined participants was 49 in April 2012, if those savings could be achieved on an ongoing basis over 20 years and reinvested at 5% annually, the accumulated benefit would amount to \$8.40M or around \$4,000 per participant. Additionally, the (unconditional) average decline in within-fund annual turnover for the Streamlined group was 11.3% (=35.2% – 23.9%). Based on the Streamlined group balance of \$603.8M at end-June 2012 and assuming round-trip within-fund transaction costs of 0.50%, this could translate into an annual aggregate cost savings of \$0.341M.<sup>16</sup> If such savings could be achieved on an ongoing basis over 20 years and reinvested at 5% annually,

---

<sup>15</sup> One might wonder whether this change for the Not-Plan-Defaulted Streamlined group could have been attributed to a rising stock market inasmuch as the S&P 500 increased 32% in 2013. Yet when we track average equity balances for each of the three groups, all three experienced similar growth over the 2013 year. So we conclude that the relative change in allocations between the Not-Plan-Defaulted Streamlined participants and the Non-Streamlined participants is due to decisions made by the participants themselves.

<sup>16</sup> We compute this as  $\$603.8 \times (0.113 \times 2 \times 0.0025)$ .

the accumulated additional benefit would be \$11.8M, or \$5,400 per participant. In total, then, the per-participant savings could be over \$9,400 per participant.

### 5.2 Changes in Portfolio Risks

We also examine how participant portfolio risks changed by comparing pre- versus post-streamlining positions. To this end, we first estimate the factor-related systematic risks and diversifiable (idiosyncratic) risks for both retained and deleted funds, using a model similar to Fama-French (1993) in which the estimated coefficients measure each fund's exposures to systematic factor risks:

$$\tilde{R}_{it} - R_{Ft} = \alpha + b_1(\tilde{R}_{Mt} - R_{Ft}) + b_2SmB_t + b_3HmL_t + b_4WmL_t + b_5Term_t + b_6Def_t + \tilde{e}_{it}$$

Here  $\tilde{R}_{it} - R_{Ft}$  refers to the excess return of fund  $i$  over the risk-free rate (the one-month Treasury bill rate from Ibbotson Associates);  $\tilde{R}_{Mt} - R_{Ft}$  refers to the value-weighted return on all NYSE, AMEX, and NASDAQ stocks (from CRSP) minus the risk-free rate;  $SmB$  refers to the difference in the performance of small relative to big stocks;  $HmL$  to the difference in performance of value stocks to growth stocks;  $WmL$  is a momentum factor premium measuring the difference in performance of past winner and past loser stocks (Carhart, 1997);  $Term$  measures the difference between the monthly long-term government bond return (from Ibbotson Associates) and the one-month Treasury bill rate measured at the end of the previous month (from the Center for Research in Security Prices, CRSP); and  $Def$  measures the difference between the return on a market portfolio of long-term corporate bonds (the Composite portfolio in the corporate bond module of Ibbotson Associates) and the monthly long-term Treasury bond return. The fund's diversifiable (idiosyncratic) risk is measured as  $\sigma(e)$ , the standard deviation of the regression residuals. These regressions are estimated using ten years of monthly fund and factor returns.

Having estimated the model parameters representing systematic and idiosyncratic risks, we next compute for each participant the systematic and idiosyncratic risks specific to his own portfolio, using his portfolio weights as of end-June 2012 and end-December 2012. Finally, we regress the post-pre changes in systematic and idiosyncratic risks on *Not-Plan-Defaulted-Streamlined*, *Plan-Defaulted-Streamlined*, and our control variables. Results appear in Table 9, where Panel A (B) reports model estimates for the shorter (longer) post-streamlining period.

[Table 9 here]

Panel A of Table 9 shows that, as a result of the reform, all Streamlined participants' portfolios (both Plan-Defaulted and Not-Plan-Defaulted) generally exhibited significantly greater reductions in systematic risk relative to the Non-Streamlined participants. Stated differently, there was a larger reduction in portfolio 'tilt' toward most systematic sources of variation for the Streamlined participants. There are two exceptions. First, relative to the non-streamlined group, there was a significant *increase* in market beta for the Plan-Defaulted Streamlined participants, in contrast to the significant decrease in market beta for the Not-Plan-Defaulted Streamlined participants. This tracks the changes in broad stock market exposure for these two streamlined groups shown in Table 8. Second, and again relative to the non-streamlined group, we find a greater *increase* (reduction) in small-cap risk exposure for the Not-Plan-Defaulted (Plan-Defaulted) Streamlined participants. The reason for this difference is not entirely clear from Tables 6 and 8 where the stock exposures and allocations are reported with insufficient granularity to differentiate the presence of small- versus large-cap stocks. One possible explanation, though, is that many of the deleted sector and international funds, in which the Not-Plan-Defaulted Streamlined group had been invested, had much lower exposures to small-cap risk.

We also find that the reform resulted in a significant reduction in idiosyncratic risk for the Streamlined group relative to its Non-Streamlined peer group, and this reduction was even more notable for the Not-Plan-Defaulted members of the Streamlined group. Moreover, the reduction in idiosyncratic risk was greater for male versus female participants, as were reductions in exposures to the market and momentum stock risk factors, and the default risk bond factor. These last two findings in the retirement plan setting agree with Barber and Odean's results (2001) for online brokerage accounts. It is also worth pointing out that many of these changes in risk exposure were most pronounced for participants with larger, versus smaller, portfolio balances.<sup>17</sup>

As was true for the observed portfolio characteristics discussed above, Panel B of Table 9 confirms that the Panel A shorter-period portfolio risk changes wrought by the reform persisted over the entire 2013 calendar year. One exception, consistent with our findings in Table 8, Panel B, is that the Not-Plan-Defaulted Streamlined participants slightly reversed their initial reduction in stock market exposure post-reform, although by the end of 2013 their market beta was still significantly smaller than before the streamlining. It is also worth noting that the reduction in idiosyncratic risk for both streamlined groups reported for the shorter interval remains significant over the longer interval, although the change was smaller. Thus the initial effects of the reform remained largely intact by the end of 2013.

To summarize the results in this section, the streamlining of the DC plan described here had a statistically significant and economically important impact on the characteristics and risk attributes of savers' accounts. First, within-fund turnover in participants' retirement portfolios (a significant cause of largely unseen transaction costs) and expense ratios were significantly

---

<sup>17</sup> This pattern aligns with results by Calvet, Campbell, and Sodini (2009) who studied Swedish investors; they found that wealthier investors rebalanced toward a riskier share when they altered their portfolios. Yet that analysis was not focused on retirement accounts, as here, however.

reduced, thereby enhancing the performance of participants' investments. This inference is consistent with much research showing that high fees and transactions costs (typically associated with active investment management) can erode the returns that mutual funds pass through to investors (e.g., Fama and French 2010; Barras, Scaillet and Wermers 2010). Recent investor trends in the mutual fund industry appear to reflect this adverse effect of excessive costs and fees – for example, during the first eleven months of 2016, passive U.S. mutual funds saw a net cash inflow of \$429 billion, compared to a \$285 billion net cash outflow from actively managed U.S. mutual funds (Dietrich, 2016). Second, the reduction in idiosyncratic risk is also beneficial to participants, an indication that their portfolios are less exposed to unnecessary risks that are diversifiable. Of course, the reduced amount of idiosyncratic risk that we report relies on the assumption that our model of systematic risks is reasonably specified. It is reassuring that much academic research in financial economics confirms the efficacy of the empirical model we employ, even though the existence of a “correct” model remains an open issue. Last, in that the changes in systematic risks that we document are compensated with corresponding changes in expected returns, it is less clear how such changes affect participants' welfare which will, in the end, be a function of their individual risk preferences. In sum, our results complement and extend previous studies suggesting that plan simplification enhances retirement saving (e.g., Beshears, Choi, Laibson, and Madrian 2013), though previous work has focused only on participation and contributions and not on asset allocation outcomes as here.

## **6. Conclusions**

This study has examined the salutary effects of streamlining the DC fund menu by deleting some funds and tiering options in an easier-to-understand format. While recent studies have

evaluated how simplification can influence retirement plan participation and contributions, they have not examined how streamlining changes investment patterns. Our analysis examines how halving the fund menu while including a new brokerage account changed investment behavior at a large nonprofit institution. We find that participants who initially held at least one deleted fund were relatively older, more likely to be male, and earned higher incomes; they also held higher balances in riskier funds and lower balances in safer/balanced/target date funds. Interestingly, in response to the changed lineup, only 9% of these participants moved money into the new brokerage window, taking only 0.4% of assets. Moreover, Streamlined participants' new allocations included significantly fewer funds and had significantly lower exposure to non-market systematic risks; they also contained a lower allocation to stocks. Streamlined participants' new allocations also led to fund holdings with significantly lower expense ratios and within-fund turnover rates, which, based on reasonable assumptions, could lead to potential accumulated savings for these participants over a 20-year period of \$20.2M, or over \$9,400 per participant.

The changes we have discerned are important, particularly given regulators' growing interest in retirement plan fees and costs, and the growing number of lawsuits citing excessive number of fund options and high fees being brought against 401(k) and 403(b) plans.<sup>18</sup> As one example, US Department of Labor guidance to plan participants alerts members to the possibility that costs may rise as investment options become more numerous.<sup>19</sup> Such costs, in turn, can reduce

---

<sup>18</sup> Firms from Oracle to Lockheed to MIT and the Lutheran Church have been targeted; see Iacurci (2016) and Bernard (2016).

<sup>19</sup>For instance, the US Department of Labor (US DOL) states on its website ([http://www.dol.gov/ebsa/publications/401k\\_employee.html](http://www.dol.gov/ebsa/publications/401k_employee.html)): "In recent years, there has been a dramatic increase in the number of investment options typically offered under 401(k) plans as well as the level and types of services provided to participants. These changes give today's employees who direct their 401(k) investments greater opportunity than ever before to affect their retirement savings. As a participant you may welcome the variety of investment options and the additional

the size of the nest egg available for retirement. Additionally, employers in their plan fiduciary capacity are charged under pension law with managing retirement plans in the best interests of participants.<sup>20</sup> Our work implies that plan sponsors would do well to recognize that the length and complexity of their plan menus matter. Accordingly, our results should be of substantial interest to those seeking to improve defined contribution retirement plan design, including employers, fund providers, consultants, and regulators.

---

services, but you may not be aware of their cost. As shown above, the cumulative effect of the fees and expenses on your retirement savings can be substantial.”

<sup>20</sup> The US DOL points out that plan sponsors must “ensure that fees paid to service providers and other expenses of the plan are reasonable in light of the level and quality of services provided; and select investment options that are prudent and adequately diversified; disclose plan, investment, and fee information to participants to make informed decisions regarding their investment options under the plan; and monitor investment options and service providers once selected to see that they continue to be appropriate choices.” ([http://www.dol.gov/ebsa/publications/401k\\_employee.html](http://www.dol.gov/ebsa/publications/401k_employee.html))
