**Hidden Regret in Insurance Markets:
Adverse and Advantageous Selection***

Rachel J. Huang¹, Alexander Muermann²,
and Larry Y. Tzeng³

March, 2008

Abstract:

We examine insurance markets with two types of customers: those who regret suboptimal decisions and those who don't. In this setting, we characterize the equilibria under hidden information about the type of customers and hidden action. We show that both pooling and separating equilibria can exist. Furthermore, there exist separating equilibria that predict a positive correlation between the amount of insurance coverage and risk type, as in the standard economic models of adverse selection, but there also exist separating equilibria that predict a negative correlation between the amount of insurance coverage and risk type, i.e. advantageous selection. Since optimal choice of regretful customers depends on foregone alternatives, any equilibrium includes a contract which is offered but not purchased.

1 Introduction

Rothschild and Stiglitz (1976) show in their classical adverse selection model in insurance markets that, in equilibrium—if it exists—lower risk individuals self-select into contracts which offer lower insurance coverage. The model thus predicts a positive correlation between the amount of insurance coverage and claim frequency. Similarly, economic models of moral hazard predict this positive relation: individuals with higher insurance coverage reduce their investments in risk-mitigating measures and thereby are of higher risk type. The empirical evidence of this relationship is mixed. In markets for acute health care insurance and annuities the empirical evidence is consistent with the prediction of adverse selection and moral hazard models (see e.g. Cutler and Zeckhauser, 2000, Mitchell, et al., 1999, Finkelstein and Porteba, 2004). In contrast, a negative relationship between insurance coverage and claim frequency exists in markets for term-life insurance, long-term care, and Medigap insurance (see e.g. Cawley and Philipson, 1999, Finkelstein and McGarry, 2006, Fang, et al., 2006). Last, Chiappori and Salanié (2000) show that in the French car insurance market the correlation between insurance coverage and claim frequency is not significantly different from zero.

de Meza and Webb (2001) argue that a negative relationship between insurance coverage and risk type—which they term *advantageous selection*—can be explained by hidden heterogeneity of individuals' degree of risk aversion. They show that there exist equilibria in which high risk-averse individuals both purchase more insurance coverage and invest more in risk-mitigating measure—thereby becoming lower risk types—than less risk-averse individuals. The empirical evidence, however, on the sign of the negative relationship between degree of risk aversion and risk type is mixed. Finkelstein and McGarry (2006) find evidence in the long-term care insurance market that is consistent with advantageous selection, i.e. more risk averse individuals are more likely to purchase long-term care insurance and less likely to enter a nursing home. In contrast, Cohen and Einav (2007) and Fang, et al. (2006) find the opposite in automobile and Medigap insurance: risk type is positively correlated with risk aversion.

In this paper, we propose hidden heterogeneity in degrees of anticipatory regret as an alternative reason for a negative relationship between insurance coverage and risk type. Regret is interpreted as the anticipated disutility incurred from an ex-ante choice that turns out to be ex-post suboptimal.

Individuals make their decision by trading off the maximization of expected utility of wealth against the minimization of expected disutility from anticipated regret. The latter is modeled as a second attribute to the utility function that depends on the difference in utilities of wealth levels derived from the foregone best alternative and derived from the actual choice.

We examine the existence and type of equilibria when insurers can neither observe this preference heterogeneity nor investment behavior in risk-mitigating measures. We show that both pooling and separating equilibria can exist. Furthermore, depending on the parameters of our model, there exist separating equilibria that predict a positive correlation between the amount of insurance coverage and risk type, as in the standard economic models of adverse selection, but there also exist separating equilibria that predict a negative correlation between the amount of insurance coverage and risk type, i.e. advantageous selection. This allows us to derive empirical predictions within our model about the sign of the relation between insurance coverage and risk type. We show that advantageous selection is observed if the cost of investing in risk-mitigating measures is relatively low and/or if the intensity of anticipatory regret is relatively high. An additional interesting empirical prediction relates to the feature of preferences incorporating regret that foregone alternatives impact individual welfare. This implies that, in any equilibrium, a contract is offered which is not purchased. This contract provides the highest net payment–indemnity net of premium–amongst all contracts offered.

Our paper contributes to the literature that examines insurance markets under asymmetric information about dimensions other than and/or in addition to risk type. Jullien et al. (2007) study a principal-agent model in which the agent has private information about his degree of risk aversion. Similar to de Meza and Webb (2001), their model can predict a positive correlation between insurance coverage and risk type. Sonnenholzner and Wambach (2006) examine equilibria in insurance markets in which customers have private information about their time preferences. They show that advantageous selection can emerge in equilibria since impatient customers might both spend less on insurance coverage and risk mitigation, thereby becoming higher risk types. In those papers, as in ours, there exists one-dimensional heterogeneity of customers who engage in potentially different, unobservable actions which endogenously imply heterogeneity in risk type. Smart (2000), Wambach (2000), and Villeneuve (2003) exogenously assume two-dimensional heterogeneity of customers with respect to risk type and risk aversion. Those models predict, as Rothschild and

Stiglitz (1976), a positive correlation between insurance coverage and risk type. Recently, Netzer and Scheuer (2007) show that by endogenizing heterogeneity in wealth levels and thereby risk aversion negative correlation between insurance coverage and risk type can be obtained.

This paper contributes to this literature by examining the degree of anticipatory regret as the source of heterogeneity. Anticipatory regret introduces two interesting and novel features. First, the relative valuation of insurance coverage between different types of customers depends on the amount of insurance coverage offered. In the existing literature, the relative valuation of insurance coverage is independent of the level of insurance coverage. Higher risk types, more risk averse individuals, or more patient individuals value insurance coverage relative more at any level of insurance coverage. Second, as mentioned above, individual welfare depends on the set foregone alternatives. This implies that insurance companies can strategically influence optimal choice by offering contracts that are not purchased in equilibrium.

Our paper also contributes to the literature on regret. Regret theory was initially developed by Bell (1982) and Loomes and Sugden (1982) and has been shown in both the theoretical and experimental literature to explain individual behavior. More recently, the impact of regret on decision making has been examined in different scenarios. Braun and Muermann (2004) and Muermann, et al. (2006) show that regret moves individuals away from extreme decisions, i.e. regret leads to more (less) insurance coverage if insurance is relatively expensive (cheap) and, similarly, regret leads financial investors to buy more (less) risky stocks if the equity risk premium is relatively high (low). In a dynamic setting, Muermann and Volkman (2006) show that anticipatory regret and pride can cause investors to sell winning stocks and hold on to losing stocks, i.e. it might help explain behavior that is consistent with the disposition effect. Regret preferences have also been applied to asset pricing and portfolio choice in an Arrow-Debreu economy (Gollier and Salanié 2006), to currency hedging (Michenaud and Solnik 2006), and to first price auctions (Filiz and Ozbay 2007).

This paper contributes to the literature above by considering the equilibrium effects under asymmetric information in a market in which both types of investors coexist, those that consider anticipated regret in their decision-making, and those that do not.

In the following section, we introduce the model and derive properties of indifference curves as those will be used for our graphical analysis of equilibria in Section 3. In Section 4 we derive

comparative statics of model parameters with respect to the existence and type of equilibria. We conclude in Section 5.

2 Model Approach

The model focuses on two types of individuals: those that regret suboptimal decisions, type R individuals, and those that do not, type N individuals. Let λ be the fraction of type R individuals in the population. Both types are endowed with initial wealth w and face a potential loss of size L with initial probability p_0 . Individuals can invest in self-protection at a disutility $f_i \in \{0, F\}$, $i = N, R$, to reduce the probability of a loss from $p(0) = p_0$ to $p(F) = p_F < p_0$. Type N individuals maximize expected utility with respect to an increasing, concave utility function $u(\cdot)$. For type R individuals, we follow Bell (1982) and Loomes and Sugden (1982) by implementing the following two-attribute utility function to incorporate regret in preferences

$$u_R(W) = u(W) - kg(u(W^{\max}) - u(W)). \quad (1)$$

Type R individuals thus maximize expected utility with respect to the utility function $u_R(\cdot)$.¹ The first attribute is the utility derived from the final level of wealth, W , and is thus equivalent to the utility of type N individuals. The second attribute accounts for the fact that the individual considers regret in his decision-making. Regret depends on the difference between the utility of wealth, W^{\max} , the individual could have obtained with the foregone best alternative (FBA) and the utility of actual final wealth, W . The function $g(\cdot)$ measures the disutility incurred from regret and we assume that $g(\cdot)$ is increasing and convex with $g(0) = 0$. This assumption is supported in the literature (Thaler, 1980, Kahneman and Tversky, 1982) and has recently found experimental support by Bleichrodt et al. (2006). Furthermore, Laciana and Weber (2008) show that the convexity of g can be justified by regret preferences to be consistent with the Allais' common consequence effect. The linear, non-negative coefficient k measures the relative importance of the second attribute regret to the first attribute.

Insurers are risk-neutral and offer insurance contracts which are specified by the amount of

¹This two-attribute utility function is consistent with the axiomatic foundation of regret developed by Sugden (1993) and Quiggin (1994).

insurance coverage, I , and the premium rate, c , per dollar of coverage. We assume that there is asymmetric information about both preferences and actions. That is, whether or not a specific individual regrets his decision and whether or not he invests in risk-mitigating measures is private information to the individual. The insurer only knows the distribution of the two types of individuals, N and R , in the population; that is, the insurer knows the parameter λ .

2.1 Investing in self-protection

The gains in expected utility for type i individuals, $\Delta_i(I, c)$, $i = N, R$, from investing in self-protection under an insurance contract (I, c) is

$$\Delta_N(I, c) = (p_0 - p_F) (u(w - cI) - u(w - L + (1 - c)I)) - F \quad (2)$$

for type N individuals and

$$\begin{aligned} \Delta_R(I, c) = & \Delta_N(I, c) - p_F g(u(W_L^{\max}) - u(w - L + (1 - c)I) + F) \\ & + p_0 k g(u(W_L^{\max}) - u(w - L + (1 - c)I)) \\ & - (1 - p_F) k g(u(W_{NL}^{\max}) - u(w - cI) + F) + (1 - p_0) k g(u(W_{NL}^{\max}) - u(w - cI)) \end{aligned} \quad (3)$$

for type R individuals. W_L^{\max} and W_{NL}^{\max} are the wealth levels under the FBA in the Loss and No-Loss state, respectively. As investing in self-protection only has ex-ante value to the insured, it is never optimal from an ex-post point of view to have invested in self-protection.² In the No-Loss state, the FBA is thus to not have invested in self-protection and to not have bought insurance coverage, i.e. $W_{NL}^{\max} = w$. In the Loss state, the FBA is to have bought the contract with the highest net coverage $(1 - \tilde{c}) \tilde{I} = \arg \max_{(I, c)} (1 - c) I$ amongst the set of contracts offered, i.e. $W_L^{\max} = w - L + (1 - \tilde{c}) \tilde{I}$. Let $X = (\tilde{I}, \tilde{c})$ denote the insurance contract with the highest net

²The assumption that regret is based only on the FBA given the realized state of nature excludes regretful feelings related to having changed the chances of a loss occurring, e.g. after a loss occurred: “I should have invested in self-protection to decrease the probability of a loss occurring.” Our qualitative results, however, are robust to those changes.

insurance coverage amongst the set of contracts offered. Therefore

$$\begin{aligned}\Delta_R(I, c) &= \Delta_N(I, c) - p_F k g \left(u(w - L + (1 - \tilde{c}) \tilde{I}) - u(w - L + (1 - c)I) + F \right) \\ &\quad + p_0 k g \left(u(w - L + (1 - \tilde{c}) \tilde{I}) - u(w - L + (1 - c)I) \right) \\ &\quad - (1 - p_F) k g (u(w) - u(w - cI) + F) + (1 - p_0) k g (u(w) - u(w - cI)).\end{aligned}\quad (4)$$

The gains from investing in self-protection is larger for type N individuals if the cost of investing in self-protection, F , is high enough. More precisely, (4) implies that $\Delta_N(I, c) > \Delta_R(I, c)$ if and only if F satisfies the following inequality

$$\begin{aligned}& p_F g \left(u(w - L + (1 - \tilde{c}) \tilde{I}) - u(w - L + (1 - c)I) + F \right) + (1 - p_F) g (u(w) - u(w - cI) + F) \\ > & p_0 g \left(u(w - L + (1 - \tilde{c}) \tilde{I}) - u(w - L + (1 - c)I) \right) + (1 - p_0) g (u(w) - u(w - cI)).\end{aligned}\quad (5)$$

To demonstrate the existence of equilibria in which there exists a negative relation between insurance coverage and risk type, i.e. *advantageous selection*, we assume that the cost of investing in self-protection, F , is high enough such that type R individuals will not find it optimal to invest in self-protection under any contract, i.e. we assume a level of F such that $\Delta_R(I, c) < 0$ for all I and c with $p_F \leq c \leq p_0$.

2.2 Demand for insurance

Braun and Muermann (2004) have shown that type R individuals “hedge their bets” by avoiding extreme decisions. That is, type R individuals purchase more (less) insurance coverage than type N individuals if it is optimal for type N individuals to purchase very little (a lot of) insurance coverage. This implies that type R individuals value insurance coverage relatively more (less) than type N individuals if an insurance contract offers very little (a lot of) coverage.

2.3 Graphical analysis

We will use graphs to analyze the existence of equilibria. In all graphs, the x -axis represents the individuals’ level of final wealth in the No-Loss state, $W_{NL} = w - cI$, whereas the y -axis denotes the individuals’ level of final wealth in the Loss state, $W_L = w - L + (1 - c)I$. The individuals’

endowment point is $(w - L, w)$ and labeled A . \mathbf{P}_F , $\bar{\mathbf{P}}$, and \mathbf{P}_0 denote the actuarially fair pricing lines with respect to the premium rates $c = p_F$, $c = \bar{p} = \lambda p_0 + (1 - \lambda) p_F$, and $c = p_0$, respectively.

Type N individuals. The levels of expected utility for type N individuals investing and not investing in self-protection under contract (I, c) are

$$EU_N(I, c, F) = p_F u(W_L) + (1 - p_F) u(W_{NL}) - F$$

and

$$EU_N(I, c, 0) = p_0 u(W_L) + (1 - p_0) u(W_{NL}).$$

The slope of type N individuals' indifference curve are

$$\left. \frac{dW_L}{dW_{NL}} \right|_{EU_N(I, c, F)} = - \frac{1 - p_F}{p_F} \frac{u'(W_{NL})}{u'(W_L)}$$

and

$$\left. \frac{dW_L}{dW_{NL}} \right|_{EU_N(I, c, 0)} = - \frac{1 - p_0}{p_0} \frac{u'(W_{NL})}{u'(W_L)}.$$

The slope of the locus of contracts under which type N individuals are indifferent between investing and not investing in self-protection, i.e. for which $\Delta_N(I, c) = 0$, is given by

$$\left. \frac{dW_L}{dW_{NL}} \right|_{\Delta_N(I, c) = 0} = \frac{u'(W_{NL})}{u'(W_L)}.$$

The line of those contracts is thus increasing and below the 45° line as $0 < \left. \frac{dW_L}{dW_{NL}} \right|_{\Delta_N(I, c) = 0} < 1$. Furthermore, for any premium rate c there exists a unique level of coverage $\bar{I}(c) < L$ such that $\Delta_N(\bar{I}(c), c) = 0$. Since $\frac{\partial \Delta_N(I, c)}{\partial W_L} < 0$ we conclude that it is optimal for types N individuals to not invest in self-protection under all contracts that are above the line of contracts for which $\Delta_N(\bar{I}(c), c) = 0$. For all contracts below this line, it is optimal for type N individuals to invest in self-protection. Note, that for all contracts with $\Delta_N(\bar{I}(c), c) = 0$, indifference curves are kinked with a steeper slope below than above as

$$\left| \left. \frac{dW_L}{dW_{NL}} \right|_{EU_N(I, c, F)} \right| > \left| \left. \frac{dW_L}{dW_{NL}} \right|_{EU_N(I, c, 0)} \right|.$$

Type R individuals. The level of expected utility of type R individuals not investing in self-protection under contract (I, c) is

$$EU_R(I, c, 0) = EU_N(I, c, 0) - p_0 k g \left(u(w - L + (1 - \tilde{c}) \tilde{I}) - u(W_L) \right) - (1 - p_0) k g (u(w) - u(W_{NL})).$$

Note that the expected utility of type R individuals and therefore the shape of the indifference curves depends upon the contract $X = (\tilde{I}, \tilde{c})$ that offers the highest net insurance coverage. The slope of type R individuals' indifference curve is

$$\frac{dW_L}{dW_{NL}} \Big|_{EU_R(I, c, 0)} = - \frac{1 - p_0}{p_0} \frac{u'(W_{NL})}{u'(W_L)} \frac{1 + k g' (u(w) - u(W_{NL}))}{1 + k g' (u(w - L + (1 - \tilde{c}) \tilde{I}) - u(W_L))} < 0. \quad (6)$$

The second derivative of type R individuals' indifference curve is given by

$$\begin{aligned} & \frac{d^2 W_L}{dW_{NL}^2} \Big|_{EU_R(I, c, 0)} \\ = & - \left(\frac{dW_L}{dW_{NL}} \Big|_{EU_R(I, c, 0)} \right)^2 \frac{u''(W_L)}{u'(W_L)} - \frac{1 - p_0}{p_0} \frac{u''(W_{NL})}{u'(W_L)} \frac{1 + k g' (u(w) - u(W_{NL}))}{1 + k g' (u(w - L + (1 - \tilde{c}) \tilde{I}) - u(W_L))} \\ & + \left(\frac{dW_L}{dW_{NL}} \Big|_{EU_R(I, c, 0)} \right)^2 u'(W_L) \frac{k g'' (u(w - L + (1 - \tilde{c}) \tilde{I}) - u(W_L))}{1 + k g' (u(w - L + (1 - \tilde{c}) \tilde{I}) - u(W_L))} \\ & + \frac{1 - p_0}{p_0} \frac{(u'(W_{NL}))^2}{u'(W_L)} \frac{k g'' (u(w) - u(W_{NL}))}{1 + k g' (u(w - L + (1 - \tilde{c}) \tilde{I}) - u(W_L))} \\ > & 0. \end{aligned}$$

Type R individuals' indifference curve are thus also both decreasing and convex.

Comparison of indifference curves between types. We next compare the slopes of the indifference curves of type R and type N individuals with contracts under which type N individuals invest in self-protection. The indifference curve of type R individuals are flatter than the one of type N individuals if and only if

$$\frac{1 - p_0}{p_0} \frac{1 + k g' (u(w) - u(W_{NL}))}{1 + k g' (u(w - L + (1 - \tilde{c}) \tilde{I}) - u(W_L))} \leq \frac{1 - p_F}{p_F}. \quad (7)$$

At the endowment point $A = (w - L, w)$ condition (7) is satisfied and the indifference curve of type R individuals are thus flatter than the one of type N individuals. The effect of increasing the amount of coverage I at the same premium rate c on the left-hand side of condition (7) is

$$\begin{aligned} & \frac{\partial}{\partial I} \left(\frac{1 + kg'(u(w) - u(W_{NL}))}{1 + kg'(u(w - L + (1 - \tilde{c})\tilde{I}) - u(W_L))} \right) = \frac{cu'(W_{NL})kg''(u(w) - u(W_{NL}))}{1 + kg'(u(w - L + (1 - \tilde{c})\tilde{I}) - u(W_L))} \\ & + \frac{(1 - c)u'(W_L)kg''(u(w - L + (1 - \tilde{c})\tilde{I}) - u(W_L))(1 + kg'(u(w) - u(W_{NL})))}{\left(1 + kg'(u(w - L + (1 - \tilde{c})\tilde{I}) - u(W_L))\right)^2} \\ & > 0. \end{aligned}$$

This implies that, for a given premium rate c and contract $X = (\tilde{I}, \tilde{c})$, condition (7) can only switch once at the unique level of insurance coverage $\hat{I} = \hat{I}(c, X)$. We thus conclude that for low levels of coverage the indifference curve of type R individuals are flatter than the one of type N individuals whereas for high levels of coverage the indifference curve of type R individuals can be steeper than the one of type N individuals. This is consistent with the result of Braun and Muermann (2004) who show that type R individuals value insurance coverage relatively more (less) than type N individuals if an insurance contract offers very little (a lot of) coverage. Valuing insurance coverage relatively more (less) implies a flatter (steeper) indifference curve.

At the level $I = \hat{I}(c, X)$, the indifference curves of type R and type N individuals have the same slope, i.e. condition (7) is satisfied with equality which implies

$$\begin{aligned} & \frac{d^2W_L}{dW_{NL}^2} \Big|_{\overline{EU_R(I,c,0)}} \\ & = \frac{d^2W_L}{dW_{NL}^2} \Big|_{\overline{EU_N(I,c,F)}} + \left(\frac{dW_L}{dW_{NL}} \Big|_{\overline{EU_R(I,c,0)}} \right)^2 u'(W_L) \frac{kg''(u(w - L + (1 - \tilde{c})\tilde{I}) - u(W_L))}{1 + kg'(u(w - L + (1 - \tilde{c})\tilde{I}) - u(W_L))} \\ & + \frac{1 - p_0}{p_0} \frac{(u'(W_{NL}))^2}{u'(W_L)} \frac{kg''(u(w) - u(W_{NL}))}{1 + kg'(u(w - L + (1 - \tilde{c})\tilde{I}) - u(W_L))} \\ & > \frac{d^2W_L}{dW_{NL}^2} \Big|_{\overline{EU_N(I,c,F)}}. \end{aligned}$$

The indifference curve of type R individuals at $I = \hat{I}(c, X)$ are thus more convex than the one of type N individuals for all premium rates c and contracts X .

Changing the foregone best alternative. An interesting feature of regret is that preferences depend upon foregone alternatives. In particular, insurance companies can change the optimal choice of type R individuals by offering a contract X with higher net insurance coverage $(1 - \tilde{c})\tilde{I}$. The impact of increasing net insurance coverage of the foregone best alternative on the slope of the indifference curve of R types is

$$\frac{\partial}{\partial (1 - \tilde{c})\tilde{I}} \left(\frac{dW_L}{dW_{NL}} \Big|_{EU_R(I,c,0)} \right) = - \frac{\partial}{\partial (1 - \tilde{c})\tilde{I}} \left(\frac{1 + kg'(u(w) - u(W_{NL}))}{1 + kg'(u(w - L + (1 - \tilde{c})\tilde{I}) - u(W_L))} \right) > 0.$$

This implies that the indifference curves of types R individuals become flatter at any contract (I, c) . The intuition is that increasing net insurance coverage of the foregone best alternative increases the regret in the Loss-state and thereby makes coverage relatively more valuable to type R individuals. This implies that offering a contract with a higher net insurance coverage increases the level of coverage $I = \hat{I}(c, X)$ at which condition (7) switches.

3 Equilibrium Analysis

We have shown that type R individuals might be both less willing to invest in self-protection and prefer less insurance coverage than type N individuals. These results suggests that there can be equilibria in which there exists a negative relation between insurance coverage and risk type, i.e. *advantageous selection*. We consider the following game between insurers and individuals:

Stage 1 Insurers make binding offers of insurance contracts specifying coverage I and premium rate c .

Stage 2 Individuals choose either a contract from the set of contracts offered or no contract. If the same contract is offered by two insurers, individuals toss a fair coin.

Stage 3 Individuals choose whether or not to invest in self-protection.

Rothschild and Stiglitz (1976) define the equilibrium set of contracts as the set of contracts such that each contract offered in equilibrium earns non-negative expected profits and such that there does not exist a contract outside the equilibrium set of contracts which earns, if added, non-negative expected profits.

As examined above, regret introduces two interesting features. First, the relative valuation of insurance coverage between the two types depends on the amount of insurance coverage offered. Types R individuals value insurance relatively more (less) than type N individuals if the level of coverage offered is small (large). Second, the foregone best alternative and thus the optimal choice of type R individuals depends on the set of contracts offered. An insurance company could thus strategically offer two contracts: one contract, contract X , is only offered to change the expected utility and thereby the optimal choice of type R individuals, and the other contract serves the purpose of attracting customers given the shift in optimal choice of type R individuals. We can restrict our strategies to those where contract X offers a higher net coverage than the other contracts offered as only then type R optimal choice will change.³

To accommodate for this strategy, we modify the equilibrium concept used by Rothschild and Stiglitz (1976) in the following way: the equilibrium set of contracts is the set of contracts such that each contract offered in equilibrium earns non-negative expected profits and such that there does not exist a pair of contracts outside the equilibrium set of contracts which each earn, if added, non-negative expected profits.⁴

3.1 Pooling equilibria

In this section, we examine the existence of pooling equilibria as a function of the level of coverage offered and via graphical analysis. The main result of this section is that, contrary to Rothschild and Stiglitz (1976) and de Meza and Webb (2001), a pooling equilibrium can exist. As defined above, contract $(\hat{I}(\bar{p}, X), \bar{p})$ denotes the contract with premium rate \bar{p} under which the indifference curve of type R individuals have the same slope than the one of type R individuals and contract $(\bar{I}(\bar{p}), \bar{p})$ denotes the contract with premium rate \bar{p} under which type N individuals are indifferent between investing and not investing in self-protection, i.e. $\Delta_N(\bar{I}(\bar{p}), \bar{p}) = 0$. As shown above, both contracts are unique.

³In the No-Loss state, the foregone best alternative (FBA) is to have rejected all insurance contracts. We implicitly assume that insurers cannot change this FBA, e.g. by offering to short-sell insurance. Equivalently, we do not allow insurers to offer insurance coverage above the loss value. We note, however, that our qualitative results are robust to those changes.

⁴If insurance companies were not allowed to offer contract X alongside with a second contract, then our results remain valid under the equilibrium concept of Rothschild and Stiglitz (1976).

Proposition 1 *Suppose that the cost of investing in self-protection, F , is high enough such that $\Delta_R(I, c) < 0$ for all I and c with $p_F \leq c \leq p_0$.*

1. *If $\hat{I}(\bar{p}, X) \geq \bar{I}(\bar{p})$ for some contract X , then there exists no pooling equilibrium.*
2. *If $\hat{I}(\bar{p}, X) < \bar{I}(\bar{p})$ for $X = (L, c')$ where c' is implicitly defined by $EU_N(\bar{I}(\bar{p}), \bar{p}, F) = EU_N(L, c', 0)$, then the contract $(\bar{I}(\bar{p}), \bar{p})$ is the unique pooling equilibrium if and only if*
 - (a) $EU_R(\bar{I}(\bar{p}), \bar{p}, 0) > EU_R(I, p_0, 0)$ for all I
 - (b) $EU_N(\bar{I}(\bar{p}), \bar{p}, F) > EU_N(I, \bar{p}, F)$ for all I that satisfy $EU_R(I, \bar{p}, 0) > EU_R(\bar{I}(\bar{p}), \bar{p}, 0)$
 - (c) $EU_N(\bar{I}(\bar{p}), \bar{p}, F) > EU_N(I, p_0, 0)$ for all I with $\Delta_N(I, p_0) < 0$

Proof. First note that no pooling equilibrium exists under which neither type R nor type N invest in self-protection. Type N individuals prefer full coverage and type R individuals prefer partial coverage as shown in Braun and Muermann (2004), i.e. for any pooling contract (I, p_0) there exist a contract to which either type R or type N individuals deviate. We can thus restrict our analysis to all contracts (I, \bar{p}) with $I \leq \bar{I}(\bar{p})$.

1. Suppose $\hat{I}(\bar{p}, X) > \bar{I}(\bar{p})$ for some contract X . This implies for any pooling contract $B = (I, \bar{p})$ we must have $I < \hat{I}(\bar{p}, X)$. We have shown above that for all $I < \hat{I}(\bar{p}, X)$ the indifference curve of type R individuals are flatter than the one of type N individuals, i.e. (7) is satisfied (see Figure 1). This implies that no pooling equilibrium exist under those contracts as a contract with slightly less coverage and a potentially different premium rate (contract D in Figure 1) attracts type N individuals but not type R individuals. Note that contract D does not change preferences of type R individuals as it offers lower net indemnity than contract B . The intuition behind this result is that for low levels of coverage $I < \hat{I}(\bar{p}, X)$ type R individuals value insurance coverage relatively more than type N individuals and can thus not be attracted by such contracts. This is equivalent to the proof in Rothschild and Stiglitz (1976) who show that under any pooling contract there exist contracts that attract low-risk types but not high-risk types as high-risk types value insurance coverage relatively more. Suppose $\hat{I}(\bar{p}, X) = \bar{I}(\bar{p})$. Contract $B = (\hat{I}(\bar{p}, X), \bar{p})$ in Figure 2 cannot be a pooling equilibrium as the indifference curve of type R individuals at $I = \hat{I}(\bar{p}, X)$ are more convex than the

one of type N individuals. This implies that there exists a contract with slightly less coverage and a potentially different premium rate which attracts type N individuals but not type R individuals (contract D in Figure 2). Again, contract D does not change preferences of type R individuals as it offers lower net indemnity than contract B .

2. Suppose $\hat{I}(\bar{p}, X) < \bar{I}(\bar{p})$ with $X = (L, c')$ where c' is defined as above. Contract X is the contract with the highest net insurance coverage such that neither type R nor type N individuals will prefer X over $(\bar{I}(\bar{p}), \bar{p})$. As argued above, any contract $B = (I, \bar{p})$ with $I < \hat{I}(\bar{p}, X)$ cannot be a pooling equilibrium. Equivalently to above, the contract $B = (\hat{I}(\bar{p}, X), \bar{p})$ is also not a pooling equilibrium (see Figure 3).

For any contract $B = (I, \bar{p})$ with $\hat{I}(\bar{p}, X) < I < \bar{I}(\bar{p})$, the indifference curve of type R individuals is steeper than the one of type N individuals, i.e. type N individuals value insurance coverage relatively more than type R individuals (see Figure 4). A contract offering slightly more coverage and a potentially different premium rate (contract D in Figure 4) attracts type N individuals but not type R individuals. Note, however, that the introduction of contract D does not change the preferences of type R individuals as contract X offers higher net insurance coverage than contract D . Thus, no pooling equilibria $B = (I, \bar{p})$ exist with $\hat{I}(\bar{p}, X) \leq I < \bar{I}(\bar{p})$.

Now let's examine contract $B = (\bar{I}(\bar{p}), \bar{p})$ (see Figure 5). Since $\hat{I}(\bar{p}, X) < \bar{I}(\bar{p})$, the indifference curve of type R individuals is steeper at B than the one of type N individuals. This implies that there does not exist any contract (I, c) with $\Delta_N(I, c) > 0$ that attracts type N individuals but not type R individuals. Condition 2c implies that any contract (I, c) with $\Delta_N(I, c) < 0$ must offer a rate $c < p_0$ to attract type N individuals and thereby make negative profits. Condition 2b ensures that no other contract (I, \bar{p}) on the price line $\bar{\mathbf{P}}$ attracts both types of individuals. Last, condition 2a implies that no contract (I, p_0) on the price line \mathbf{P}_0 attracts type R individuals. Therefore, $B = (\bar{I}(\bar{p}), \bar{p})$ constitutes a pooling equilibrium under those conditions.

■

In the pooling equilibrium, type R individuals value insurance coverage relatively less than type N individuals, i.e. the amount of insurance coverage must be relatively high. Offering less coverage

would be relatively more attractive to type R individuals and, under the conditions above, yield negative expected profits. Offering more coverage would induce type N individuals to not invest in self-protection and also imply negative expected profits.

3.2 Separating equilibria

In this section, we examine the existence and type of separating equilibria. We assume that each contract offered and chosen by individuals must earn non-negative expected profits. We thus do not allow for cross-subsidization between types as it is examined, for example, in Miyazaki (1977), Spence (1978), and Crocker and Snow (1985).

Under the assumption that type R individuals do not invest in self-protection, the contract chosen by type R individuals in equilibrium is priced at the rate $c = p_0$ and offers the optimal amount of coverage $I_R^* = I_R^*(p_0, X)$, given contract X offering the highest net insurance coverage. Let us denote this contract by $R = (I_R^*(X), p_0)$. As shown by Braun and Muermann (2004), the optimal amount of coverage at a fair rate is less than full coverage, i.e. $I_R^*(p_0, X) < L$ for all X . As optimal amount of coverage depends on contract X , three contracts might be offered in separating equilibria: contract N and R chosen by types N and R individuals, respectively, and the “optimal choice changing” contract X which is not chosen by any type of individual. In equilibrium, contract X must offer the highest net insurance coverage such that neither type chooses the contract.⁵

In the following proposition we show that there exists a separating equilibrium under which both types do not invest in self-protection and both types receive the optimal amount of coverage given the rate $c = p_0$.

Proposition 2 *Suppose that the cost of investing in self-protection, F , is high enough such that $\Delta_R(I, c) < 0$ for all I and c with $p_F \leq c \leq p_0$. Then the two contracts $N = (L, p_0)$ and $R = (I_R^*(p_0, X), p_0)$ constitute a separating equilibrium if and only if $EU_N(L, p_0, 0) > EU_N(I, \bar{p}, F)$ for all $I \leq \bar{I}(\bar{p})$ that satisfy $EU_R(I, \bar{p}, 0) \geq EU_R(I_R^*(p_0, X), p_0, 0)$.*

Proof. Figure 6 illustrates the equilibrium. In this scenario, the contract X with the highest net insurance coverage coincides with contract N . The additional condition outlined in the proposition

⁵Suppose contracts X' and $R(X') = (I_R^*(p_0, X'), p_0)$ are offered. Then offering a contract X with higher net insurance coverage than X' together with contract $R(X) = (I_R^*(p_0, X), p_0)$ attracts type R individuals since the optimal amount of insurance coverage is increasing in the net insurance coverage of the foregone best alternative in the Loss-state.

assures that no pooling contract can attract both types of individuals while making zero expected profits. ■

In the separating equilibrium outlined above, both types of individuals do not invest in self-protection but purchase different amounts of insurance coverage. Note that both types receive their first-best contracts under the same premium rate. The empirical prediction under this scenario is that both types are of identical risk-type and that type R individuals purchase less insurance coverage than type N individuals.

3.2.1 Advantageous selection

In the following proposition, we show that there exist and characterize separating equilibria that predict a negative relationship between insurance coverage and risk type, i.e. *advantageous selection*. As above, we denote the amount of coverage $\bar{I} = \bar{I}(c)$ under which type N individuals are indifferent between investing and not investing in self-protection, i.e. under which $\Delta_N(\bar{I}(c), c) = 0$.

Proposition 3 *Suppose that the cost of investing in self-protection, F , is high enough such that $\Delta_R(I, c) < 0$ for all I and c with $p_F \leq c \leq p_0$. Then the three contracts N , R , and X constitute a separating equilibrium with advantageous selection if and only if under one of the following two scenarios:*

1. $N = (\bar{I}(p_F), p_F)$, $X = (L, c)$, and $R = (I_R^*(p_0, X), p_0)$ where

(a) c satisfies $EU_N(\bar{I}(p_F), p_F, F) = EU_N(L, c, 0)$ and $c \leq p_0$

(b) $EU_R(I_R^*(p_0, X), p_0, 0) \geq EU_R(\bar{I}(p_F), p_F, 0)$

2. $N = (\bar{I}(c_N), c_N)$, $X = (L, c)$, and $R = (I_R^*(p_0, X), p_0)$ where

(a) c_N satisfies $EU_R(\bar{I}(c_N), c_N, 0) = EU_R(I_R^*(p_0, X), p_0, 0)$

(b) c is the minimum rate that satisfies both $EU_N(\bar{I}(c_N), c_N, F) \geq EU_N(L, c, 0)$ and

$EU_R(I_R^*(p_0, X), p_0, 0) \geq EU_R(L, c, 0)$, and $c \leq p_0$

(c) $EU_R(\bar{I}(\bar{p}), \bar{p}, 0) \leq EU_R(I_R^*(p_0, X), p_0, 0) \leq EU_R(\bar{I}(p_F), p_F, 0)$

(d) $EU_N(\bar{I}(c_N), c_N, F) \geq EU_N(I, p_0, F)$ where I satisfies $EU_R(I_R^*(p_0, X), p_0, 0) = EU_R(I, p_F, 0)$

$$(e) \quad EU_N(\bar{I}(c_N), c_N, F) \geq EU_N(I, \bar{p}, F) \text{ for all } I \leq \bar{I}(\bar{p}) \text{ that satisfy } EU_R(I, \bar{p}, 0) \geq EU_R(I_R^*(p_0, X), p_0, 0)$$

Proof.

1. Figure 7 illustrates the equilibrium. Condition 1b represents the property that the indifference curve of type R individuals through contract R crosses the locus of contracts $\Delta_N(I, c) = 0$ above the line \mathbf{P}_F . Contract N is then the best contract for type N individuals among the set of contracts on \mathbf{P}_F that are not preferred by type R individuals over contract R . Contract $X = (L, c)$ is the contract with highest net coverage that is not preferred by either type over their respective equilibrium contract. The condition $c \geq p_0$ assures that contract (L, p_0) does not attract type N individuals.
2. Figure 8 illustrates this equilibrium. Condition 2a defines contract N . Condition 2c represents the property that the indifference curve of type R individuals through contract R crosses the locus of contracts $\Delta_N(I, c) = 0$ below the line \mathbf{P}_F but above the line $\bar{\mathbf{P}}$. Conditions 2d and 2e assure that type N individuals do neither prefer contract N' nor prefer any pooling contract (I, \bar{p}) that would also be taken by type R individuals over contract N .

■

The key factor that allows for separating equilibria with advantageous selection is the fact that type R individuals prefer partial coverage at a fair rate. Type N individuals can separate themselves from type R individuals with more insurance coverage since they value insurance coverage relatively more at the fair rate. Both equilibrium 1 and equilibrium 2 in the above proposition have interesting features.

In equilibrium 1, the presence of type R individuals in the market does not cause any negative externality on type N individuals. The equilibrium contracts $N = (\bar{I}(p_F), p_F)$ and $R = (I_R^*(p_0, X), p_0)$ are identical to the equilibrium contract under hidden action if there were only one type of customers in the market. Equilibrium 1 is in fact the only equilibrium with that feature.

In equilibrium 2, insurance companies make strictly positive expected profits with contract N while they break even with contract R . However, this is true only under pure separation and also due to the fact that we do not allow for cross-subsidies between types. This implies that there exist

semi-separating equilibria under the conditions outlined in equilibrium 2 in which a certain fraction of type R individuals choose contract N . The maximum fraction of those types is determined by the break-even condition of insurance companies for contract N .

3.2.2 Adverse selection

In this section, we characterize the separating equilibrium that predicts a positive relationship between insurance coverage and risk type, i.e. *adverse selection*.

Proposition 4 *Suppose that the cost of investing in self-protection, F , is high enough such that $\Delta_R(I, c) < 0$ for all I and c with $p_F \leq c \leq p_0$. Then the three contracts $N = (I_N, p_F)$, $R = (I_R^*(p_0, X), p_0)$, and $X = (L, c)$ constitute a separating equilibrium with adverse selection if and only if*

1. (a) I_N satisfies $EU_R(I_N, p_F, 0) = EU_R(I_R^*(p_0, X), p_0, 0)$
- (b) c is the minimum rate that satisfies both $EU_N(I_N, p_F, F) \geq EU_N(L, c, 0)$ and $EU_R(I_R^*(p_0, X), p_0, 0) \geq EU_R(L, c, 0)$, and $c \leq p_0$
- (c) $EU_R(I_R^*(p_0, X), p_0, 0) \leq EU_R(\bar{I}(p_F), p_F, 0)$
- (d) $EU_N(I_N, p_0, F) \geq EU_N(\bar{I}(c_{N'}), c_{N'}, F)$ where $c_{N'}$ satisfies $EU_R(I_R^*(p_0, X), p_0, 0) = EU_R(\bar{I}(c_{N'}), c_{N'}, 0)$
- (e) $EU_N(\bar{I}_N, p_F, F) \geq EU_N(I, \bar{p}, F)$ for all $I \leq \bar{I}(\bar{p})$ that satisfy $EU_R(I, \bar{p}, 0) \geq EU_R(I_R^*(p_0, X), p_0, 0)$

Proof. Figure 9 illustrates this equilibrium. Condition 1a defines contract N . Condition 1c precludes equilibrium 1 with advantageous selection in Proposition 3. Conditions 1d and 1e assure that type N individuals do neither prefer contract N' nor prefer any pooling contract (I, \bar{p}) that would also be taken by type R individuals over contract N . ■

Under the conditions outlined in the above proposition, the “advantageously selecting” contract $N = (\bar{I}(c_N), c_N)$ in Proposition 3 under equilibrium 2 is relatively too expensive such that type N individuals prefer not to self-select into the contract with higher coverage but rather self-select into the contract $N = (I_N, p_F)$ which offers partial coverage at their respectively fair rate p_F .

4 Comparative Statics

In this section, we discuss comparative statics of the model with regard to the types of equilibrium examined in Section 3. In our model, the type of market equilibrium varies with cost of investing in self-protection, F , the intensity of regret of type R individuals, as measured by the linear coefficient k , and the fraction of type R individuals in the population, λ .

4.1 Cost of investment in self-protection

If the cost of investing in self-protection, F , is extremely high or low both types of individuals optimally do not invest or invest in self-protection. Individuals are therefore heterogeneous only regarding their preferences but not regarding their risk type. Thus, type N individuals optimally obtain full coverage, whereas type R individuals optimally obtain partial coverage, as shown by Braun and Muermann (2004).

Case 1 *For very small (high) levels of F , it is optimal for both type R and type N individuals to invest (to not invest) in self-protection and the unique equilibrium is a separating equilibrium in which both types receive the optimal amount of coverage at the rate $c = p_F$ ($c = p_0$), i.e. full coverage for type N and partial coverage for type R individuals.*

Suppose that the cost of investing in self-protection is in a range such that we obtain equilibria under which type R individuals do not invest in self-protection but type N individuals do. As the cost F increases, the set of contracts under which it is optimal for type N individuals to invest in self-protection decreases, i.e. the locus of contracts $\Delta_N(I, c) = 0$ shifts down (see Figure 10 with $F_1 < F_2 < F_3$). We then derive the following comparative statics assuming the equilibrium exists.

Case 2 *Suppose that the cost of investing in self-protection, F , is high enough such that $\Delta_R(I, c) < 0$ for all I and c with $p_F \leq c \leq p_0$.*

1. *For low levels of F (e.g. F_1 in Figure 10), condition 1b in Proposition 3 is satisfied - i.e. type R indifference curve crosses $\Delta_N(I, p_0) = 0$ line above the pricing line \mathbf{P}_F - and a separating equilibrium with advantageous selection as in Figure 7 is obtained.*

2. For medium levels of F (e.g. F_2 in Figure 10), condition 2c in Proposition 3 is satisfied - i.e. type R indifference curve crosses $\Delta_N(I, p_0) = 0$ line below the pricing line \mathbf{P}_F and above $\bar{\mathbf{P}}$ - and a separating equilibrium with advantageous selection as in Figure 8 is obtained.
3. For high levels of F (e.g. F_3 in Figure 10), either a separating equilibrium as in Figure 9 or a pooling equilibrium as in Figure 5 is obtained.

4.2 Intensity of regret

We measure the intensity of regret by the linear coefficient k . From the slope of type R individuals' indifference curve (see equation 6) we deduce that the higher the coefficient k the steeper the indifference curves of type R individuals. Furthermore, a higher k implies a lower level of optimal insurance coverage for type R individuals as shown by Braun and Muermann (2004). Figure 11 illustrates the comparative statics with respect to k ($k_3 > k_2 > k_1$ - thus $R_3 < R_2 < R_1$).

Case 3 Suppose that the cost of investing in self-protection, F , is high enough such that $\Delta_R(I, c) < 0$ for all I and c with $p_F \leq c \leq p_0$.

1. For high levels of k (e.g. k_3 in Figure 11), condition 1b in Proposition 3 is satisfied - i.e. type R indifference curve crosses $\Delta_N(I, p_0) = 0$ line above the pricing line \mathbf{P}_F - and a separating equilibrium with advantageous selection as in Figure 7 is obtained.
2. For medium levels of k (e.g. k_2 in Figure 11), condition 2c in Proposition 3 is satisfied - i.e. type R indifference curve crosses $\Delta_N(I, p_0) = 0$ line below the pricing line \mathbf{P}_F and above $\bar{\mathbf{P}}$ - and a separating equilibrium with advantageous selection as in Figure 8 is obtained.
3. For low levels of k (e.g. k_1 in Figure 11), either a separating equilibrium as in Figure 9 or a pooling equilibrium as in Figure 5 is obtained.

4.3 Fraction λ of type R individuals in the population

In Rothschild and Stiglitz (1976), the separating equilibrium does not exist if the fraction of high risk type individuals in the population is too low. The reason behind this non-existence result is that a pooling contract not only attracts high risk individuals but also low risk individuals since the

pooling premium rate is just slightly above the fair premium rate for low risk individuals. However, pooling equilibria do not exist either.

This is different in our setting since pooling equilibria do exist (see Proposition 1). First note that the existence of both the separating equilibrium of Proposition 2 (Figure 6) and the separating equilibrium with advantageous selection of Proposition 3.1 (Figure 7) is independent of the level of λ . However, the existence of the separating equilibrium with advantageous selection of Proposition 3.2 (Figure 8) and the one with adverse selection of Proposition 4 (Figure 9) depends on the level of λ . For high level of λ , those separating equilibria exist. For low level of λ , a pooling contract attracts both types of individuals and thus no separating equilibrium exist. However, this pooling contract then constitutes a pooling equilibrium, as depicted in Figure 5, if type N individuals value insurance coverage relatively more than type R individuals at this pooling contract, i.e. if $\hat{I}(\bar{p}, X) < \bar{I}(\bar{p})$ where $\hat{I}(\bar{p}, X)$, $\bar{I}(\bar{p})$, and X are defined in Proposition 1. Otherwise, if $\hat{I}(\bar{p}, X) \geq \bar{I}(\bar{p})$ for some contract X , then neither a separating nor a pooling equilibrium exists in those situations.

5 Conclusion

The markets for annuities, long-term care insurance, and Medigap insurance have become increasingly important for societies whose population is aging, as e.g. in the US and Europe. Surprisingly, the demand for these insurance products is very low (see e.g. Mitchell, et al., 1999, Brown and Finkelstein, 2004) which might put a huge burden on future generations. Whether public or private insurance provision is more efficient depends on the underlying inefficiencies in these markets, a large part of which is due to asymmetric information. Interestingly, those markets exhibit contrasting characteristics with respect to the relation between insurance coverage and claim frequency. Understanding the reasons behind those differences is highly relevant for the design of governmental policies aimed at reducing inefficiencies due to informational asymmetries.

In this paper, we propose heterogeneous, hidden degrees of aversion towards anticipatory regret as a rationale for self-selection in insurance markets. In our equilibrium analysis, we have shown that both pooling and separating equilibria can exist. Furthermore, there exist separating equilibria of both types, advantageous and adverse selection. We have characterized the conditions for each type of equilibrium and examined the comparative statics with respect to the model's parameters.

Figure 1: No Pooling Equilibrium for $I < \hat{I}$: type N individuals invest in self-protection, whereas type R individuals do not. Indifference curve of type R individuals is flatter at B than that of type N individuals. Contract D attracts type N individuals but not type R individuals.

Figure 2: No Pooling Equilibrium for $I = \hat{I} = \bar{I}$: type N individuals invest in self-protection, whereas R type individuals do not. Indifference curve of type R and type N individuals have the same slope but are more convex at B . Contract D attracts type N individuals but not type R individuals.

Figure 3: No Pooling Equilibrium for $I = \hat{I} < \bar{I}$: type N individuals invest in self-protection, whereas type R individuals do not. Indifference curve of type R and type N individuals have the same slope but are more convex at B . Contract D attracts type N individuals but not type R individuals.

Figure 4: No Pooling Equilibrium at $\hat{I} < I < \bar{I}$: type N individuals invest in self-protection, whereas type R individuals do not. Indifference curve of type R individuals is steeper at B than that of type N individuals. Contract D attracts type N individuals but not type R individuals.

Figure 5: Pooling Equilibrium (\bar{I}, \bar{p}) : type N individuals are indifferent between investing and not investing in self-protection under B , type R individuals do not invest in self-protection. Indifference curve of type R individuals is steeper at B than that of type N individuals and type R prefer contract B over any contract on \mathbf{P}_0 . Note that contract D cannot be offered to attract type N individuals and induces them to not invest in self-protection and the company offering D would make losses.

Figure 6: Separating Equilibrium: both types of individuals do not invest in self-protection and receive their respectively optimal amount of insurance coverage.

Figure 7: Separating Equilibrium with advantageous selection 1: type N individuals invest in self-protection, whereas type R individuals do not. Type N individuals obtain more insurance coverage than type R individuals.

Figure 8: Separating Equilibrium with advantageous selection 2: type N individuals invest in self-protection, whereas type R individuals do not. Type N individuals obtain more insurance coverage than type R individuals.

Figure 9: Separating Equilibrium with adverse selection: type N individuals invest in self-protection, whereas type R individuals do not. Type N individuals obtain less insurance coverage than type R individuals.

Figure 10: Comparative statics with respect to F - $F_1 < F_2 < F_3$.

Figure 11: Comparative statics with respect to intensity of regret - $k_3 > k_2 > k_1$.
