# Summary

The epithelial absorbing cells of the small intestinal villi, the enterocytes, are the main protagonists for the transport of nutrients from the intestinal lumen to the interstitial fluids. The oriented flow of nutrients is carried out by different and complementary transport systems present in the apical and the basolateral domains of the enterocyte's plasma membrane. One of the distinctive characteristics of those intestinal cells is the presence of numerous structurally distinct protrusions (referred as microvilli) on the apical surface of the plasma membrane. They confer the brush-like appearance of the microvillus border (commonly referred to as the "brush border") typically observed in the light microscope.

Over the years, there has been considerable interest to study the molecular mechanisms driving the transport of molecules across the intestinal brush border membrane (BBM). Defects have been described to cause a variety of pathological conditions, such as disorders in the metabolism of saccharides (glucose and galactose malabsorption, lactose intolerance), amino acids (Hartnup disease, aminoacidurias), ions (sodium and potassium in the case of familiar diarrhea), metals (zinc in acrodermatitis enteropathica) and cholesterol lipids (cardiovascular diseases). In particular, the essential role of the BBM in regulating the delicate balance between cholesterol influx and efflux from the lumen to the enterocyte has been recently highlighted through the genetic analysis of individuals suffering of cholesterol disorders as well as in several clinical studies involving the use of dietary plant sterols (phytostrerols) or specific protein inhibitors blocking essential components of the cholesterol absorption/resorption pathway.

Most studies aimed at studying the enterocyte BBM have been conducted through gene analysis, activity tests and immunology assays. Its characterization at the protein level, however, has been hampered by the difficulty to isolate a pure fraction from the small intestine and by the nature of the targets of interest, being most of them transmembrane integral proteins. Predictably, the few proteomics studies reporting the identification of proteins localized in the BBM membrane failed to identify transporters and receptors that are known to be located in this fraction. Also, the very aggressive environment to which the enterocyte is exposed combined with the class of proteolytic enzymes present in this membrane imply the use of targeted strategies to maintain the structural integrity of the BBM proteins in the isolation protocol.

The primary goal of this study was the development and the evaluation of mass spectrometrybased analytical strategies for the analysis and the identification of hydrophobic proteins, such as found in the enterocyte BBM. Analysis of membrane proteins in a complex mixture has always represented an obstacle in the proteomics field. Their hydrophobic nature requests a detergent for their solubilization and makes the use of traditional proteomics techniques less compatible (e.g. two-dimensional gel electrophoresis) while their low abundance in complex biological mixtures (in comparison to soluble proteins) requires additional purifications steps for their enrichment. Even at equal abundance, the identification rate of membrane proteins is lower than that of soluble proteins. The development of an optimized sample preparation protocol combined with a robust analytical method was expected to enable the investigation of proteins located in the BBM and so to confirm the findings of several other studies, namely, that the BBM contains proteins that participate in cholesterol regulation in the enterocytes. Finally, a third goal of this study was to investigate conditions for which a quantitative mass spectrometric experiment using a label-free strategy could be used to investigate biological samples, as technical variability and sample stability of the BBM preparation were not known. The reproducibility of the technical steps had to be monitored for the whole workflow, from the BBM preparation until the mass spectrometric analysis of the samples, so to pinpoint difficulties and limitation of the workflow and preparing the way for a label free quantification strategy using only the information from the LC-MS data.

In this study, an analytical strategy enabling for the first time (to my knowledge) the direct characterization of BBM proteins previously described to participate in cholesterol absorption is presented. Key points of this strategy consisted of an improved protocol to reproducibly isolate and purify BBM preparations from the intestinal tissue, the design of an inhibitor cocktail specifically aimed at minimizing the proteolytic activity of the BBM endogeneous proteases, a targeted strategy to enrich the BBM transmembrane proteins from common cytosolic contaminants, and the use of a very robust and sensitive instrumentation using capillary liquid chromatography and tandem mass spectrometry. In particular, the original protocol from Kessler et al for purifying and enriching the proteins contained in the BBM fraction was significantly improved and extended to selectively remove cytosolic and basolateral contaminants. Whole intestine, or scrapped mucosa thereof for higher purity, was first lysed and a crude membrane fraction was isolated by differential centrifugation. The resulting pellet was then resuspended and the basolateral membrane fraction was specifically removed from the preparation by CaCl<sub>2</sub> precipitation. The enriched BBM vesicles were then pelleted by centrifugation and subjected to additional washes in high salt and high pH to remove the remaining cytosolic and membrane-associated proteins. The performance of the protocol and the purity of the obtained BBM vesicles were monitored by Western Blot

analysis following a known basolateral (Na<sup>+</sup>/K<sup>+</sup> ATPase a1) and BBM markers (FATP-4). The new protocol provided a 30- to 50-fold enrichment factor (versus about a 10-fold enrichment factor following the Kessler protocol) compared to the crude lysate while a known basolateral marker, Na<sup>+</sup>/K<sup>+</sup> ATPase a1, remained undetected in the purified BBM fraction. Simultaneously, a significant part of the protocol optimization was devoted to the inhibition of the endogenous BBM vesicles proteases, most of them of the His-Zn dependent metalloprotease superfamily that are not inhibited by common Serine, Cysteine proteinase inhibitors. Partial inhibition (approximately 90%) was achieved by adding amastatin, a known partial inhibitor, and several peptide substrates in all buffers used in the BBM purification protocol. In addition, excess calcium (a known activator of this family of proteases) was removed by adding EDTA in the first wash step immediately following the calcium precipitation step.

A tripilicate analysis of a purified mouse BBM fraction resulted in the reliable identification of 1460 proteins, of which 260 proteins were predicted to be transmembrane integral proteins. A detailed GO analysis revealed that the proteins identified in this study were equally distributed between plasma membrane, the ER/Golgi/endosome compartments, cytoskleleton and mitochondria while only a guarter of the BBM proteins were annotated as cytoplasmic. Using this protocol, a number of proteins known to play a critical role in cholesterol absorption were identified directly for the first time at the protein level. For example, the Niemann-Pick C1-like 1 protein (NPC1L1), an abundant protein of the BBM preparation, is a 13-transmembrane segments protein described to play a critical role in cholesterol absorption. Similarly, the two half-size, 6-transmembrane segments ABC transporters ABCG5 and ABCG8 are involved in the biliary secretion of cholesterol and plant sterols. The complex formed by Caveolin-1 and Annexin-2 has been suggested as key element for the cholesterol trafficking from the BBM to the endoplasmic reticulum while SR-BI, a 4-transmembrane segments receptor, has been found to be involved in cholesterol uptake. The role of many of the proteins mentioned above and of several other proteins, such as CD36, Galectin-4, and ABCB1, is the subject of hot debates. Several studies have supported their involvement in cholesterol absorption but their precise mechanisms of action have remained unclear so far. Finally, it is worth mentioning here the presence of three lipoproteins, ApoA-I, ApoA-IV and ApoE, within the identified proteins of the BBM preparation. Their confident identification in this membrane preparation was rather unexpected as lipoproteins are by nature small, soluble proteins secreted by the liver and, therefore, they are not considered as constituents of the

BBM. Rather, their presence might be due to their tight interaction with some BBM constituents, such as LRP-1 and Cubilin, which are known to interact with apoliproproteins.

The complexity of the present proteomics workflow raised the question whether it was possible to reproducibly and quantitatively survey hundreds of membrane proteins simultaneously in the enterocyte BBM vesicles. Some key parts of the study were therefore analyzed in greater details using the protein identification information (comparing the successful MS/MS analysis between bands) and comparative analysis of the precursor ion signals to investigate in a more systematic manner the factors weighting in the reproducibility of the overall analysis. Using both strategies, most of the technical steps, such as the LC-MS/MS identification strategy, the separation of complex protein mixtures by 1-D-SDS-PAGE, or the in-gel digestion of proteins using trypsin, were not identified as major contributors to the overall variability of the experiment if appropriately controlled. Taken as a whole, the systematic evaluation of the overall analytical process unambiguously confirmed the high reproducibility achieved by the LC-MS/MS process. Rather, the BBM isolation protocol itself was identified as a potential source of variability due to its relative length and complexity and due to the inclusion of several steps that might have been difficult to carry on quantitatively, such as the CaCl<sub>2</sub> precipitation step. Also, the remaining proteolytic activity of the abundant BBM proteases, if unchecked, could also contribute to sample degradation and add extensive variability to the protein identification process. Finally, the variability in the number of commonly identified proteins was significantly lower when samples were compared to each other using a proper design of experiment.

In conclusion, this study demonstrates the feasibility to reproducibly and quantitatively analyze membrane proteins in complex mixture such as isolated from the enterocyte BBM. Key elements for a successful analysis were a robust sample preparation protocol yielding highly enriched BBM vesicles, a tightly controlled analytical strategy, and a statistically driven data analysis scheme. In particular, and most importantly, in this BBM vesicle preparation highly enriched for membrane proteins, the number of different peptides and the average sum of peptide counts were reflective for the relative abundance of a given membrane protein in the preparation, independently of its number of transmembrane segments. However, those identified tryptic peptides were exclusively located within the loops or in the cytoplasmic regions of membrane proteins. Assuming that trypsin cleaves off transmembrane helices, that is, the transmembrane tryptic peptide is generated during the digestion procedure, the rather hydrophobic nature and the length (30-40 amino acids in average) of most of those peptides may hinder their extraction from the gel band or they may stick tube walls during

peptide extraction. Finally, very long and/or hydrophobic peptides might not be amenable to the standard RP-LC-MS/MS conditions used in this study. In this respect, the use of a different stationary phase, such as HILIC, might provide additional and complementary peptide information.

Finally, this study opens the way for additional proteomics experiments focused on the BBM biology that will contribute and complement existing studies about inhibition of cholesterol absorption that have been focused so far at the gene expression level. In a preliminary experiment, the BBM preparations from an ApoE knockout mice (one of the most widely used mouse models to study dislipidemia in which the targeted deletion of the *apoE* gene leads to severe hypercholesterolemia and spontaneous atherosclerosis) and a wild type mouse of the same genetic background were compared. In the absence of biological replicates, only "black and white" differences were considered. Most interestingly, the Ileal Bile Acid Transporter (IBAT) protein and the ApoAI protein, which were robustly identified in the wild type animals, couldn't be detected in the ApoE knockout mice. This finding was not described in any of the earlier published studies and strongly suggests a disruption of the bile acids metabolism in the knockout animal. In conclusion, the analytical strategy described in this study was shown sufficiently mature to perform comprehensive comparative analysis of mice that have, for example, been treated with specific compound or subjected to different diets. In due course, this study could has been followed by a full fledge proteomics study in which a much more comprehensive biological experiment could have been investigated, such as a control mouse vs statins vs ezetimibe treatment, and where the impact of those drugs in the BBM (unknown at present) could have been investigated in more detail.

# Zusammenfassung

Die absorbierenden Epithelzellen der Dünndarmzotten, die Enterozyten, spielen beim Transport der Nährstoffe vom intestinalen Lumen zu den interstitiellen Flüssigkeiten eine zentrale Rolle. Der gerichtete Fluss von Nährstoffen wird durch verschiedene komplementäre Transportsysteme gewährleistet, welche in den apikalen und basolateralen Domänen der Plasmamembrane der Enterozyten angesiedelt sind. Eine der besonderen Eigenschaften dieser Zellen ist das Vorkommen von zahlreichen Ausbuchtungen mit charakteristischer Struktur, sogenannten Mikrovilli, auf der apikalen Oberfläche der Plasmamembran. Diese verleihen dem Mikrovillusrand (auch als "Bürstensaum" bezeichnet) das bürstenartige Aussehen, das im Lichtmikroskop typischerweise sichtbar ist.

Es besteht seit Jahren ein starkes Interesse an der Erforschung der molekularen Mechanismen, die für den Transport der Moleküle durch die intestinale Bürstensaum-Membran verantwortlich sind. Defekte in diesen Transportmechanismen können eine Vielzahl von pathologischen Problemen auslösen, wie zum Beispiel Störungen im Metabolismus von Sacchariden (Glukose- und Galaktose-Fehlabsorption, Lactoseunverträglichkeit), von Aminosäuren (Hartnup Krankheit, Aminoazidurie), von Ionen (Natrium und Kalium bei Durchfall), von Metallen (Zink bei acrodermatitis enteropathica) und von Cholesterinlipiden (Herzgefäßkrankheiten). Insbesondere wurde vor Kurzem die wesentliche Rolle der Bürstensaum-Membran bei der Regulierung des empfindlichen Gleichgewichts zwischen Cholesterinaufnahme und -abgabe zwischen Lumen und Enterozyten hervorgehoben, einerseits durch die genetische Analyse von Einzelpersonen, die an Cholesterinstoffwechsel-Störungen leiden, andererseits durch einige klinische Studien, die die Effekte von diätetischen Pflanzensterolen (phytosterols) oder spezifischen Proteininhibitoren auf wesentliche Komponenten der Cholesterinaufnahme-Systeme untersucht haben.

Die Untersuchung der Bürstensaummembran ist in den meisten Studien mittels genetischer Analysen, Aktivitätstests und immunologischer Methoden durchgeführt worden. Deren Charakterisierung auf der Proteinebene wurde bisher durch den Umstand erschwert, dass eine Membran-Präparation von Dünndarm im geeigneten Reinheitsgrad sehr anspruchsvoll war, und weil die meisten Zielproteine integrale Membranproteine sind. In den wenigen existierenden Proteomik-Studien der Bürstensaummembran wurden bezeichnenderweise die meisten Transportproteine und Rezeptoren nicht identifiziert, die in dieser Fraktion erwartet würden. Das aggressive Umfeld und die proteolytischen Enzyme, denen die Enterozyten in dieser Membran ausgesetzt sind, erfordern eine eigene Herangehensweise, um die strukturelle Integrität der Bürstensaum-Membranproteine im Isolationsprotokoll zu erhalten.

Hauptziel dieser Studie war die Entwicklung und die Evaluierung Das von massenspektrometrischen Vorgehensweisen für die Analyse und Charakterisierung von hydrophoben Proteinen, wie sie zum Beispiel in den Enterozyten der Bürstensaummembran vorkommen. Die Analyse von Membranproteinen in einem komplexen Gemisch ist seit jeher eine Herausforderung in der Proteomik. Die Hydrophobizität von Membranproteinen erfordert den Einsatz von Detergenzien für ihre Solubilisierung, was den Gebrauch von traditionellen Proteomik-Techniken (z.B. der zweidimensionalen Gelelektrophorese) erschwert. In komplexen biologischen Proteingemischen ist ihre Konzentration im Vergleich zu löslichen Proteinen niedrig, weshalb zusätzliche Reinigungsschritte für ihre Anreicherung nötig sind. Selbst bei ähnlichen Konzentrationen ist die Identifikationsrate für Membranproteine niedriger als diejenige für lösliche Proteine. Die Entwicklung eines optimierten Isolationsprotokolls in Kombination mit einer robusten analytischen Methode sollte demnach die Untersuchung von Bürstensaum-Membranproteinen ermöglichen. Dadurch könnten die Ergebnisse anderer Studien bestätigt werden, die zeigen, dass die Bürstensaum-Membranproteine enthält, die an der Cholesterinregelung in den Enterozyten beteiligt sind. Ein drittes Ziel dieser Studie war herauszufinden, unter welchen Bedingungen biologische Proben ohne den Einsatz von Isotopen-markierten Standards massenspektrometrisch quantifiziert werden können. Da weder die technische Reproduzierbarkeit noch die Stabilität der Bürstensaummembran-Präparation bekannt waren, musste die Reproduzierbarkeit der technischen Schritte für den vollständigen Arbeitsablauf überwacht werden, von der Bürstensaummembran-Präparation bis zur massenspektrometrischen Analyse der Proben, um rechtzeitig Schwierigkeiten und Einschränkungen zu identifizieren, die eine reine LC-MS-Quantifizierungsstrategie beeinträchtigen könnten.

In dieser Untersuchung wird (meines Wissens nach) erstmals ein analytisches Vorgehen beschrieben, welches die direkte Charakterisierung von Bürstensaum-Membranproteinen ermöglicht, deren Beteiligung bei der Cholesterinsynthese bereits beschrieben worden ist. Die Hauptelemente dieses Vorgehens sind ein verbessertes Protokoll, um reproduzierbar Bürstensaummembran-Präparation aus Dünndarmgewebe zu isolieren und aufzureinigen, das Design eines Proteaseninhibitorencocktails, der spezifisch die proteolytische Aktivität der endogenen Proteasen der Bürstensaum-Membran minimiert, ein gezieltes Vorgehen, um Bürstensaum Transmembranproteine aus den üblichen zytosolischen Kontaminanten aufzureinigen, und schliesslich die Verwendung eines robusten und empfindlichen

Instrumentariums auf der Basis von Kapillar-Flüssigchromatographie und Tandem-Massenspektrometrie. Insbesondere wurde das Protokoll von Kessler et al für die Aufreinigung und Anreicherung der Proteine in der Bürstensaum-Membran deutlich verbessert und ausgedehnt auf die gezielte Entfernung von zytosolischen und basolateralen Verunreinigungen. Ganze Dünndärme, oder zur Erhöhung der Reinheit davon abgeschabte Dünndarmschleimhaut, wurde zuerst lysiert und eine Rohmembranfraktion wurde durch differentielle Zentrifugierung isoliert. Das Pellet wurde resuspendiert und die basolaterale Membranfraktion gezielt durch CaCl<sub>2</sub>-Fällung entfernt. Die angereicherten Bürstensaummembran-Vesikel wurden durch Zentrifugation sedimentiert und bei hoher Salzkonzentration und hohem pH-Wert gewaschen, um verbleibende zytosolische und membranassoziierte Proteine zu entfernen. Die Effizienz des Protokolls und die Reinheit der erhaltenen Bürstensaummembran-Vesikeln wurden durch Western-Blot-Analyse des bekannten basolateralen Markerproteins Na<sup>+</sup>/K<sup>+</sup> ATPase a1 und des Bürstensaummembran-Markers FATP-4 überprüft. Das neue Protokoll ergab einen 30- bis 50-fachen Anreicherungsfaktor (im Vergleich zu einem 10-fachen Anreicherungsfaktor nach Anwendung des Kessler-Protokolls) bezogen auf das Rohlysat, wobei der basolaterale Marker,  $Na^+/K^+$  ATPase a1, in der gereinigten Bürstensaummembran-Fraktion nicht mehr nachgewiesen werden konnte. Besondere Beachtung wurde bei der Protokoll-Optimierung der Inhibition der endogenen Bürstensaum-Membran Proteasen geschenkt, von denen die meisten der His-Zn-abhängigen Metalloproteasen-Superfamilie angehören, welche nicht auf gewöhnliche Serin- und Cystein-Protease-Inhibitoren reagieren. Durch die Zugabe von Amastatin, eines bekannten Teilinhibitors, und verschiedener Peptidsubstrate in alle Puffer des Bürstensaummembran-Aufreininigungsprotokolls wurde eine partielle Inhibition von etwa 90% erzielt. Ausserdem wurde das überschüssige Kalzium (ein bekannter Aktivator dieser Protease-Familie) durch Zugabe von EDTA im ersten Waschschritt direkt im Anschluss an die Kalzium-Fällung entfernt.

Eine Analyse mit Triplikaten der aufgereinigten Maus Bürstensaummembran-Fraktion ergab 1460 zuverlässig identifizierte Proteine, von welchen 260 Proteine als integrale Transmembranproteine vorhergesagt wurden. Eine detaillierte Aufschlüsselung gemäss Genontologie ergab, dass sich die Proteine gleichmässig über die Plasmamembran, ER/Golgi/Endosom Kompartimente, das Zellskelett und die Mitochondrien verteilen, während nur ein Viertel der Bürstensaummembran-Proteine als zytoplasmatisch annotiert werden. Mittels dieses Protokolls wurden mehrere Proteine, welche bei der Cholesterinaufnahme eine wichtige Rolle spielen, erstmals auf Proteinebene direkt

19

identifiziert. Ein Beispiel dafür ist das Niemann-Pick C1-like 1 (NPC1L1) Protein, ein Protein mit 13 Transmembran-Domänen, welches in der Bürstensaummembran-Präparation stark vertreten war und das in der Literatur als zentral bei der Cholesterinaufnahme beschrieben wird. Gleiches gilt für die beiden ABC Transporter ABCG5 und ABCG8, die an der biliären Sekretion von Cholesterin und planzlichen Sterolen beteiligt sind. Dem aus Caveolin-1 and Annexin-2 bestehenden Komplex wurde ebenfalls eine zentrale Rolle für den Cholesterintransport von der Bürstensaummembran zum endoplasmatischen Retikulum zugewiesen, während SR-BI, ein 4-Transmembrandomänen-Rezeptor, an der Cholesterinaufnahme beteiligt sein soll. Die Rolle vieler der oben erwähnten und weiterer Proteine wie zum Beispiel CD36, Galectin-4, und ABCB1 ist Gegenstand intensiver Diskussionen. Verschiedene Studien belegen ihre Beteiligung an der Cholesterinaufnahme, aber ihr genaues Wirkprinzip ist noch unklar. Bemerkenswert ist ausserdem der eindeutige Nachweis von drei Lipoproteinen, ApoA-I, ApoA-IV and ApoE, unter den identifizierten Proteinen der Bürstensaummembran-Präparation. Ihr Nachweis war kaum zu erwarten, da Lipoproteine kleine, lösliche, von der Leber sekretierte Proteine sind und deshalb nicht als Bestandteile der Bürstensaummembran gelten. Ihr Vorkommen dürfte einer engen Interaktion mit bestimmten Bürstensaummembran-Komponenten wie z.B. LRP-1 und Cubilin zuzuschreiben sein, von welchen bekannt ist, dass sie mit Apolipoproteinen interagieren.

Angesichts der Komplexität der genutzten Proteomik-Vorgehensweise stellte sich die Frage, ob es möglich ist, reproduzierbar und quantitativ Hunderte von Membranproteinen gleichzeitig zu untersuchen. Einige Schritte wurden deshalb besonders gründlich analysiert, einerseits anhand der Protein-Identifikationen (Vergleich der MS/MS-Resultate zwischen Banden) und andererseits anhand des Peptidsignals, um systematisch die massgeblichen Faktoren für die Reproduzierbarkeit der Gesamtanalyse festzustellen. In beiden Fällen konnte gezeigt werden, dass die meisten technischen Schritte, wie z.B. das Verfahren für LC-MS/MS Identifikationen, die Auftrennung komplexer Proteingemische anhand von 1D-SDS-PAGE oder der In-Gel-Verdau von Proteinen mittels Trypsin, nur wenig zur Gesamtvariabilität beitrugen, sofern sie angemessen kontrolliert wurden. Die hohe Reproduzierbarkeit des LC-MS/MS-Prozesses konnte dabei bestätigt werden. Hingegen konnte das Bürstensaummembran-Protokoll als mögliche Quelle der Variabilität identifiziert werden, da es relativ lang und komplex ist und Schritte enthält, deren Reproduzierbarkeit schwer zu gewährleisten ist, z.B. die CaCl<sub>2</sub>-Fällung. Ausserdem könnten Überreste proteolytischer Aktivität aus den stark vertretenen Proteasen Probenabbau bewirken und dadurch die Reproduzierbarkeit des Protein-Identifikationsprozesses beträchtlich verringern. Die

Variabilität der Anzahl der Proteine, die in allen Proben gemeinsam identifiziert wurden, war aber bei der Verwendung einer optimierten Versuchsplanung deutlich geringer.

Die vorliegende Arbeit zeigt, dass Membranproteine in einem komplexen Gemisch wie z.B. einem Isolat aus der Enterozyten-Bürstensaummembran reproduzierbar und quantitativ analysiert werden können. Entscheidend für den Erfolg der Analyse sind ein robustes Probenaufbereitung-Protokoll, um stark angereicherte Bürstensaummembran- Vesikeln zu erhalten, eine engmaschige Kontrolle der Analyseschritte und ein statistisch abgesichertes Vorgehen bei der Auswertung. Besonders wichtig zu bemerken ist, dass in diesen stark mit angereicherten Bürstensaummembran-Vesikeln die Membranproteinen Anzahl unterschiedlicher Peptide und die durchschnittliche Summe der Anzahl Peptide die relative Abundanz jedes Proteins widerspiegelt, unabhängig von der Anzahl seiner Transmembran-Segmente. Allerdings stammen die identifizierten tryptischen Peptide ausschliesslich von Schleifen oder zytoplasmatischen Bereichen des Membranproteins. Wenn man annimmt, dass Trypsin Transmembranhelices spaltet, d.h. dass Transmembranpeptide während des Verdaus entstehen, so ist es gut möglich, dass die hydrophoben Eigenschaften und die Länge der meisten dieser Peptide (durchschnittlich 30-40 Aminosäuren) die Extraktion aus der Gel-Bande erschweren, oder sie könnten während der Peptid-Extraktion an der Gefässwand haften bleiben. Ausserdem ist nicht klar, ob sehr lange oder hydrophobe Peptide unter den üblichen RP-LC-MS/MS-Bedingungen analysierbar sind. Unter diesem Gesichtspunkt könnte der Einsatz einer anderen stationären Phase wie z.B. HILIC zusätzliche, komplementäre Peptidinformation liefern.

Diese Arbeit schafft auch eine Grundlage für zukünftige Proteomik-Experimente mit Schwerpunkt auf der Bürstensaummembran-Biologie, welche bereits existierende, auf Genexpressions-Daten basierte Studien zur Inhibition von Cholesterinabsorption vertiefen und ergänzen. In einem Vorexperiment wurden Bürstensaummembran-Präparationen einer ApoE Knockout-Maus und einer Wildtyp-Maus mit demselben genetischen Hintergrund untersucht. Die ApoE Knockout-Maus ist eines der am meistverbreiteten Mausmodelle um Dislipidämie zu untersuchen, wobei eine gezielte Deletion des apoE-Gens eine schwere Hypercholesterämie und spontane Atherosklerose auslöst. Da biologische Replikate fehlen wurden nur "schwarz-weisse" Unterschiede betrachtet. Interessanterweise konnten das Ileal-Bile-Acid-Transporter(IBAT)-Protein und das ApoAI-Protein in der ApoE-Knockout-Maus nicht nachgewiesen werden, während es bei Wildtyp-Mäusen durchwegs nachweisbar war. Dieser Befund ist in keiner der früher publizierten Untersuchungen beschrieben und deutet stark auf eine schwere Störung des Gallensäuren-Metabolismus im Knockout-Tier hin. Zusammenfassend kann gesagt werden, dass das analytische Vorgehen in der vorliegenden Arbeit eine umfassende vergleichende Analyse von Mäusen erlaubt, die z.B. mit bestimmten Wirkstoffen oder Futterzusammensetzungen behandelt wurden. Dieser Untersuchung könnte eine breit angelegte Proteomik-Studie folgen, in welcher ein viel umfassenderes biologisches Experiment untersucht würde, z.B. ein Vergleich zwischen Mäusen mit Statin-Behandlung, Ezetimibe-Behandlung und einer Kontrollgruppe von unbehandelten Mäusen. Der bislang unbekannte Effekt dieser Wirkstoffe auf die Bürstensaum-Membran könnte damit detaillierter untersucht werden.

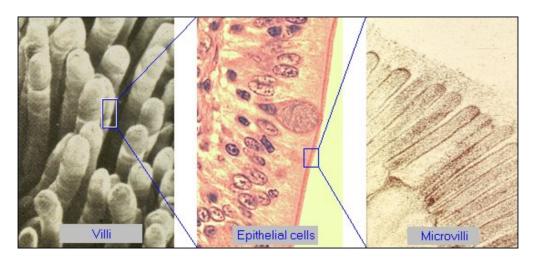

# **1. INTRODUCTION**

# 1.1 Brush Border Membrane BBM

### 1.1.1 Physiology of the small intestine

The small intestine is the longest section of the digestive tube and consists of three segments forming a passage from the pylorus to the large intestine. The duodenum is a short section starting immediately after the stomach and which receives secretions from the pancreas and liver via the pancreatic and common bile ducts. It is followed by the jejunum, considered to be roughly 40% of the small intestine in man, but closer to 90% in animals, and by the ileum, which connects to the large intestine. The ileum is considered to be about 60% of the intestine in man. However, veterinary anatomists usually refer to it as being only the short terminal section of the small intestine.

The structure of the small intestine looks on the first sight quite similar to other regions of the digestive tube. However, three features account for its huge absorptive surface area. The inner surface of the small intestine is not flat but wrinkled into circular folds (mucosal folds), which increase its surface area several-folds. The mucosa itself is composed of multitudes of projections (villi) which protrude into the lumen and are covered with epithelial cells. Finally, the lumenal plasma membrane of those absorptive epithelial cells is also folded and densely-packed in microdomains named "microvilli", whose border is commonly referred to as the **''brush border''** due to its appearance in the microscope (see Fig. 1.1).

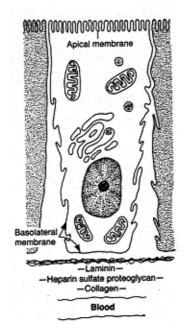

**Figure 1.1:** *The small intestine inner surface. The panels above depict the bulk of the small intestine surface area expansion, showing villi, the epithelial cells that cover the villi, and the microvilli of the epithelial cells (downloaded from web site <u>http://www.vivo.colostate.edu:80/hbooks/pathphys/digestion/smallgut/anatomy.html</u>).* 

The epithelial cells of the small intestine mature into absorptive epithelial cells that cover the villi. These are the cells that take up and deliver to the blood stream virtually all nutrients from the diet. Two other major cell types populate the small intestinal epithelium: the enteroendocrine cells which, as part of the enteric endocrine system, sense the lumenal environment and secrete hormones such as cholecystokinin and gastrin into blood; and the Goblet cells, which secrete lubricating mucus into the intestinal lumen.

### **1.1.2 Brush Border Membrane: Location and Function**

Intestinal epithelial cells are polar in their cellular organization. The intestinal brush border (synonyms: microvillus, luminal, apical) membranes of the enterocytes differ in protein and lipid composition from the inner side of the plasma membrane, the basolateral membrane (BLM) (see Fig. 1.2). The apical surface of polarized intestinal epithelial cells (the surface facing the intestinal lumen) is characterized by structurally distinct cell protrusions referred as microvilli or brush border membranes (BBMs), responsible for digestion and absorption of nutrients.

**Figure 1.2:** Schematic representation of a typical intestinal epithelial cell. The apical membrane (BBM) has a different protein and lipid composition from the basolateral membrane. The BBM can be isolated from the BLM using protocols that take advantage of the difference in polarity between the two membranes (figure downloaded from web site: <u>http://www.vivo.colostate.edu:80/hbooks/pathphys/digestion/smallgut/anatomy.html</u>).

The processing capacity of enterocytes is directly proportional to the surface of absorptive epithelia BBM. BBM are supported by cytoskeletal actin filaments which are organized into

both more or less permanent and rapidly rearranging bundles. Cytoskeleton bundles are in turn interconnected with transmembrane protein complexes forming a highly organized import–export membrane interface specialized for a variety of digestive and absorptive functions, such as protein and peptide degradation, absorption of minerals, amino acids, sugars, lipids and cholesterol (1). Shortcomings in these mechanisms may cause a variety of pathological conditions such as disorders in the metabolism of saccharides (glucose galactose malabsorption, lactose intolerance) amino acids (Hartnup disease, aminoacidurias), ions (sodium and potassium in the case of familiar diarrhea), metals (zinc in acrodermatitis enteropathica) and cholesterol lipids (cardiovascular diseases).

Recently, several proteomics studies have reported the identification of proteins localized in the BBM membrane (2, 3). Until now, however, these approaches have failed to identify transporters and receptors that are known to be located in the BBM membrane based on kinetic studies, immunological assays and in gene data, probably because of the complexity of the analyzed samples.

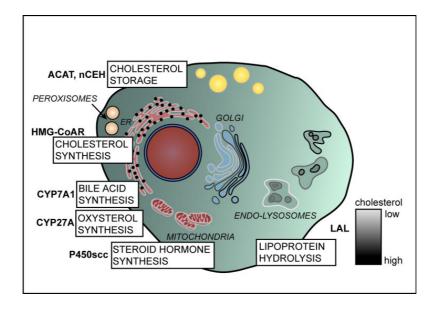

#### 1.1.3 Brush Border Membrane and Lipid Rafts microdomains

Recent studies have suggested that plasma membranes might be organized into heterogeneous functional microdomains. One type of these microdomains, called lipid rafts, is stated to be enriched in glycosphingolipids/cholesterol and in typical sets of proteins, among them also cholesterol transporters (4). Lipid rafts can be isolated by taking advantage of their resistance to nonionic detergent extraction at cold and by their differential buoyancy on a density gradient ultracentrifugation. The lipid rafts hypothesis was originally proposed to explain how proteins and lipids were sorted to the apical surface of polarized cells. However, in recent years, several functions including signaling, cholesterol homeostasis, cell trafficking or even docking sites on mammalian cells for certain pathogens and toxins have also been attributed to lipid rafts (5, 6). Despite accumulated experimental data from biophysical, biochemical, and fluorescent microscopy studies supporting the fact that lipid rafts may exist in vivo, the lipid rafts hypothesis remains controversial at least for their size, stability and the mechanism of their formation (7).

Lipid rafts isolated from the BBM have also been the subject of several recent proteomics studies (3, 8, 9). While these studies have reported the identification of proteins that were localized in the lipid rafts, almost none of these proteins were described to be involved in cholesterol absorption, a major area of interest for the analysis of the lipid rafts.

# **1.2 Cholesterol homeostasis**

The view of cholesterol as a nasty substance clogging arteries and causing heart disease is probably the one aspect that is better known to the general public. However, besides its unflattering reputation, cholesterol fulfills many other roles and is a vital component of cell membranes without which the cell would not function. It is also the precursor to all steroid hormones, bile acids and oxysterols, which by themselves are important regulatory molecules in many metabolic pathways.

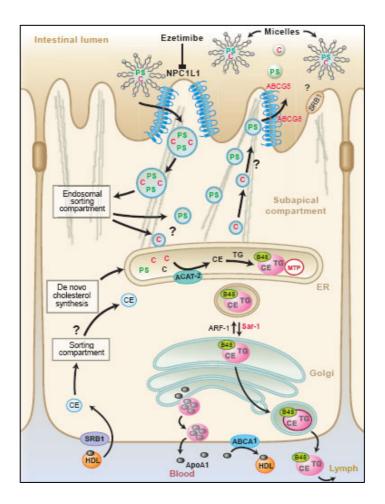

**Figure 1.3:** Cellular cholesterol distribution and key enzymes of cellular cholesterol metabolism. The approximate cholesterol content of the membrane is indicated by shades of gray. The main processes of cholesterol metabolism, key enzymes involved, and their subcellular locations are indicated. Key enzyme in the cholesterol synthesis is hydroxymethylglutaryl COA reductase (HMG-CoAR). The 3'-OH group of cholesterol is esterified by the enzyme acyl-CoA: cholesterol acyltransferase (ACAT). The enzyme responsible for cholesterol can be converted to bile salts via two pathways: the classic pathway, involving the key regulatory enzyme CYP7A1 hydrolase, and the alternative pathway, probably related to the oxysterol synthesis, involving the key enzyme sterol 27-hydroxylase (CYP27A), located in the mitochondria. Cholesterol is an obligatory precursor for steroid hormone production (figure adapted from Ikonen Elina, (10))

Endogenous cholesterol is synthesized mainly in the liver in a regulated pathway. The 27carbon tetracyclic cholesterol molecule is synthesized from acetate in a series of ~30 enzymatic reactions. The ER is the primary production site of cholesterol and the key ratelimiting enzyme of this pathway is the ER-located hydroxymethylglutaryl COA reductase (HMG-CoAR) (figure 1.3). The sub-compartmentalization of the cholesterol biosynthetic pathway remains poorly understood as of today. In general body cholesterol is primarily of endogenous origin and its homeostasis involves the movement of cholesterol between peripheral tissues and the liver (11). The liver regulates the *de novo* synthesis of cholesterol and the excretion of cholesterol into bile (directly or after conversion to bile acids), the secretion of cholesterol into blood as very low-density lipoproteins (VLDL), the modulation of receptor-mediated cholesterol uptake, the formation of esterified cholesterol (CE) and the storage of cholesterol. The intestine regulates cholesterol absorption and excretion into feces (12).

#### 1.2.1 Cholesterol absorption in the Small Intestine

Intestinal cholesterol absorption is a complex process that involves multiple interrelated sequential degradative and synthetic pathways, many of them not yet clearly defined. This biological process has attracted the interest of many pharmaceutical companies because it might provide multiple therapeutic targets in the management of patients with hypercholesterolemia.

Dietary cholesterol is absorbed from bile salt micelles with fatty acids and lysophospholipids in the proximal part of the small intestine. Key proteins involved in dietary cholesterol uptake by the enterocytes have been identified during the past few years and, in particular, the important role that the NPC1L1 protein plays in this process (13). The NPC1L1 protein is localized in the brush-border membrane of enterocytes and has been shown to be required for intestinal uptake of both cholesterol and plant sterols (14). Recent evidence suggests that this protein is the target of the cholesterol-lowering drug ezetimibe (15). Whether NPC1L1 functions as a genuine cholesterol transporter, promoting cholesterol transfer through the plasma membrane, or is indirectly involved in the process is not yet known. In addition, the ABC transporter family half-transporters ABCG5 and ABCG8 (sterolin-1 and sterolin-2) constitute a functional heterodimeric unit limiting sterol absorption (16). The role of ABCG5 and ABCG8 in dietary cholesterol absorption may not be direct, that is, by inhibiting dietary cholesterol uptake by enterocytes; rather, this transporter appears to stimulates hepatic sterol excretion into the bile and thereby modulates the bile-acid/sterol ratio, possibly to promote the secretion of absorbed sterols from the intestinal epithelium back into the gut lumen (17). Fig 1.4 summarizes in more detail the cholesterol and sterols absorption in the enterocytes and possible proteins and pathways that are associated to this process.

**Figure 1.4:** Absorption of dietary cholesterol and noncholesterol sterols in enterocyte. NPC1L1, expressed at the apical surface of enterocytes, may be the transporter that selectively absorbs dietary cholesterol (C) from micelles in the lumen of the small intestine, a step that is blocked by the drug ezetimibe. In this model, the NPC1L1 transporter permits the uptake of cholesterol (and noncholesterol sterols) into vesicles that then move through a subapical endosomal sorting compartment. Mutations in either of the transporters ABCG5 or ABCG8 cause the hyperabsorption of dietary plant sterols (PS) and other noncholesterol sterols from the small intestine, resulting in the human disease sitosterolemia. The endosomal sorting compartment allows cholesterol to progress to the endoplasmic reticulum (ER), where it is esterified (CE) by ACAT-2 and then transferred to chylomicrons (pink) ready for secretion into the bloodstream; plant sterols are shunted through a pathway resulting in their transport back to the gut lumen via ABCG5 and ABCG8. Cholesterol that is synthesized de novo is also esterified by ACAT-2 and enters chylomicrons (figure adapted from Klett E.L. et al,(18))

#### **1.3 Membrane proteomics**

#### **1.3.1 Proteomics – Definition and workflow**

The genomic sequencing of numerous organisms has radically transformed biological and medical research, providing the foundation for the large-scale interpretation of gene and cellular function. In this context, the term "proteome", coined in 1994 by Marc Wilkins (19), describes the entire **prote**in complement of the gen**ome**. Proteomics, the studies of the proteome, encompass the identification, characterization and quantification of the complete set of proteins expressed in the lifetime of a given cell, tissue or organism, including isoforms, polymorphisms and modifications, protein-protein interactions and the structural description of proteins and their complexes. Most biological functions are carried out by proteins, and to understand how cells work, one must study which proteins are present, what they do, and how they interact with one another. If the genome represents the words in a dictionary, then the proteome provides the definitions, while the interactions of the proteins with one another and with the other molecules in their environment provide the grammar to form a meaningful language.

Proteomics would not be possible without the previous achievements of genomics, which provide the information about the large, but finite number of gene products that are the focal point of proteomics studies. The challenges of proteomics are larger and far more complex than the huge but basically straightforward task of mapping the genome. In contrast to the static nature of the genome, which is essentially identical in every cell of an organism, the proteome is dynamic, constantly changing and responding to internal and external stimuli. Proteomics must deal with unavoidable problems of limited and variable sample material, sample degradation, vast dynamic range (more than  $10^{12}$  orders of magnitude for protein abundance in plasma), a multitude of post-translational modifications, almost endless tissue, developmental and temporal specificity, and disease and drug perturbations.

Proteomics represents nowadays a large family of partially overlapping areas of interest evolving along with technology breakthroughs, bioinformatics advances, and certainly also with the personal interests of investigators. Some of those areas of application are mass spectrometry-based proteomics, proteome-wide biochemical assays, systematic structural biology and imaging techniques, proteome informatics, and clinical applications of proteomics. The divisions between these areas are somewhat arbitrary, not least because technological breakthroughs often find immediate application on several fronts. More important, biologically useful insights into protein function often emerge from the combination of different proteomic approaches. This study is mostly focused in mass spectrometry-based proteomics and this area will be discussed in more details in the following paragraphs.

All proteomics experiments aim, in an ideal setting, to monitor quantitatively a full proteome at any time point of an experiment. However, the sheer complexity and dynamic range of an unfractionated proteome makes it technically impossible to address all its constituents simultaneously by any direct analytical means. As a result, it is often one of the most critical steps of a proteomics experiments to knowingly restrict the scope of the experiment to a biochemical-relevant sub-proteome that can be effectively monitored by the chosen analytical approach. A criterion often used in this process is to take advantage of some prior knowledge to "bias" the experiment towards a protein population of interest, for example by limiting the proteomics analysis towards a specific cell compartment (organelle-based proteomics), by isolating proteins with specific physical-chemistry characteristics (cytosolic proteins, membrane proteins, cytoskeleton, etc.), or even to only consider proteins captured through specific interaction ("affinity" proteomics, chemical proteomics, etc.). The achieved analytical level of precision increases generally in pair with the degree of fractionation obtained, albeit sometimes at the danger of excluding an important (and usually unknown) aspect of the experiment to follow. Conversely, a comprehensive survey of a broadly-chosen proteomics experiment might require the analysis of so many different fractions (to ensure the monitoring of a significant portion of the proteome of interest) that such an experiment might not be practicable anymore from a technical point-of-view.

Almost all mass spectrometry-based proteomic approaches are performed at the peptide level as the MS analysis of whole proteins (the so-called top-down approach) is less sensitive and the deconvolution of the generated multiply charged species is very difficult to handle from a bioinformatics point-of-view. A protein mixture of interest, isolated from a cell lysate, tissues, or enriched by a biochemical fractionation or affinity selection, is very often analyzed as a final fractionation step by 1D or 2D gel electrophoresis. Proteins are then in-gel digested (in the rare case an electrophoretic step is omitted, the proteins are then directly digested) and the extracted peptides can then be fractionated again by liquid chromatography before being analyzed by mass spectrometry. The types of chromatography and mass spectrometer that are used for an experiment depend mostly on the complexity and the type of questions that need to be answered for given analytical strategy.

The ability of mass spectrometers to quantitatively analyze ever smaller amounts of proteins from increasing complex mixture at a very high level of precision has been a primary driving force in this proteomics approach. In the last 2 years, new bioinformatics tools and the extended use of statistics in data processing and data analysis have enabled the design and execution of proteomics experiments that would not have been thinkable even 5 years ago. In particular, the high mass accuracy (below 2 ppm via Lock Mass injection, (20)) and the extended dynamic range shown by the newest generation of mass spectrometers now allow the statistical evaluation of the quality and the significance of a protein identification (via its constitutive peptides), while simultaneously being able to measure ion current of peptide ions at an unprecedented level of precision.

#### **1.3.2 Membrane Proteins - Importance and Characteristics**

Membranes play a critical role in cellular structure by providing a physical barrier between the cell and its environment and the various subcellular compartments within eukaryotic cells. Although the basic structure and function of biological membranes is provided by the lipid bilayer, membrane-spanning proteins confer unique compartment-specific functions and communication between separated environments.

The plasma membrane provides a physical boundary between the cell and its environment, playing important roles in many fundamental biological processes such as cell-cell interactions, signal transduction, and material transport. The plasma membrane components have been extensively targeted for drug design; in particular, plasma membrane proteins may account for up to 70% of all known drug targets (e.g., HER2- and G protein-coupled receptors). For example, identification of overexpressed plasma membrane proteins in diseased cells could provide protein targets for the design of either therapeutic monoclonal antibodies or small-molecule drugs.

Membrane proteins are by definition proteins that are associated with the membrane. However, in this context, the concept "associated" relates to several different situations. In a first case, the polypeptide chain spans the lipid bilayer a certain number of times and proteins belonging to this category are defined as "integral" or "intrinsic" membrane proteins. In a second case, the membrane-associated protein might be physically coupled to the membrane, whereas the association is mediated by a post-translation modification of the polypeptide, for example the grafting of a fatty acid, a polyisoprenyl chain, or through glycolipid anchors, such as the glycosylphosphatidyl inositol modification common in eukaryotic species. Such proteins are defined as "membrane-anchored" proteins. Finally there are proteins that are associated to a membrane due to their interaction with other membrane proteins or some specific lipids, but which contain neither transmembrane domains nor lipid modifications. Such proteins are typically referred to as "membrane-associated".

The transmembrane domains of integral proteins can typically fold to form either an  $\alpha$ -helix or a  $\beta$ -sheet secondary structure.  $\alpha$ -helices are formed by the consecutive joining of mostly non-polar amino acids, with typically 15-25 amino acids required to span the membrane bilayer. These amino acids exhibit positive hydropathy values and hence are the major contributors to the hydrophobic character of the membrane proteins.  $\beta$ -sheet transmembrane domains are formed by alternating polar and non-polar amino acids in the amino acid sequence. Polar amino acid side chains face the aqueous channel while the side chain of the non-polar amino acids interface with the lipid bilayer. This type of proteins is considerably less hydrophobic than  $\alpha$ -helical integral proteins. Proteins with  $\beta$ -sheet transmembrane segments tend to form a  $\beta$ -barrel structure that allows the passage of defined molecules. Structural prediction software for membrane proteins predicts nowadays quite successfully proteins with transmembrane  $\alpha$ -helix structure but typically don't consider the  $\beta$ -sheet type.

#### **1.3.3 Proteomic approaches for Membrane Proteins**

Although the analysis of soluble proteins by mass spectrometry-based proteomics technologies has made rapid progress in recent years, the analysis of membrane proteins has lagged behind and their identification is typically underrepresented in datasets. Thus, the portion of membrane proteins reported in existing analysis is much lower than the 20–30 % predicted by the human genome (21).

Traditionally the analysis of complex protein mixtures has been carried out using gel-based methods (22). Unfortunately, the well-known, highly-resolving two-dimensional IEF/SDS gel electrophoresis method has never been successfully applied for the separation of membrane proteins (23). Many hydrophobic proteins do not solubilize well in the non-ionic detergent required for the isoelectric focusing step and the few that survived this process tend to precipitate at their isoelectric point. In many studies, this separating method has been replaced by the more robust SDS-based one-dimensional gel coupled with mass spectrometry (24). Alternatively, several authors have described alternate two-dimensional gel electrophoresis separation technique, such as the so-called two dimensional blue native/SDS electrophoresis method (25) or diagonal SDS-PAGE electrophoresis (26).

Membrane proteins (and their derived hydrophobic peptides) tend to show the same trends if a reverse-phase liquid chromatography separation step is used instead. Several approaches have

attempted to overcome this problem by using either strong organic acid-cyanogen bromide (27), detergents (28), acid labile surfactants (29), organic solvents (30), salts, or high pH conditions (31) to solubilize membrane proteins. Although these methods proved to be efficient one way or the other, they were usually bound with other disadvantages that limited their usefulness. The presence of detergents affects the performance of chromatographic separation and also leads to mass spectral signal suppression. Commonly-used proteases, like trypsin, cannot be used for digestion of proteins when organic acids are used due to low pH conditions, or the enzyme activity is significantly reduced in presence of high percentage of organic solvents. High pH-based methods use proteinase K to cleave proteins non-specifically at random amino acid sequences, which makes the resulting peptide mixture extremely complex to analyze. In general, all methods described above require extensive sample handling to make the sample compatible for mass spectral analysis.

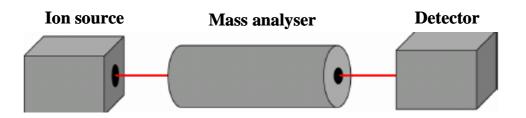

In summary, it is clear that there is a strong need for a simple and efficient method to analyze membrane proteins. The first step in this direction is the development of a suitable protocol for the enrichment of membrane proteins. As membrane proteins are typically lower in abundance then compared to soluble proteins, a biochemical fractionation method taking advantage of their unique physical-chemical properties is required to overcome their otherwise rather limited dynamic range in the analysis.

### **1.4 Mass spectrometry**

Mass spectrometry has been the analytical workhorse tool for biologists over the last quarter century. As its name implies, the mass spectrometer is an instrument to measure the mass of a substance. Initially used for the analysis of small, volatile molecules, its use has quickly become ubiquitous in the "biological" world with the invention of ionization sources compatibles with the analysis of the "big" molecules in the 1980s.

Mass spectrometers have been used over the last hundred years for a wide variety of applications, ranging from estimating the masses of elements and their isotopes to small molecule identification and characterization to modern day proteomics analysis. According to the time period and the need, mass spectrometry and mass spectrometers have evolved. Various types of mass spectrometers exist today to address a wide variety of applications ranging from analyzing the soil of alien worlds in space research to structural characterization of complexes of proteins.

All mass spectrometers consist of three basic components (Fig. 1.5). An ion source ionizes first the molecules to analyze, then a mass analyzer separates the generated ions according to their mass-to-charge ratio (m/z) and a detector measures the ion beam current. Each of these elements exists in several different forms so that a wide variety of mass spectrometers may exist to fulfill different needs.

*Figure 1.5:* Schematic representation of the components of a mass spectrometer (Adapted from Lottspeich and Zorbas (32)).

Mass spectrometers are operated under vacuum (ranging from  $10^{-4}$  for ion traps to  $10^{-10}$  Torr for FT-based instruments) to prevent the loss of the ions by collision with a gas molecule.

#### 1.4.1 A brief history of MS in biology

First attempts to analyze intact peptides by mass spectrometry were achieved using fast atom bombardment (FAB) ionization, which was first described in 1981 by Barber and co-workers (33). This ionization method was able to desorb (for the time) rather large molecules in the mass range of 2000–17000 Da depending on the sensitivity required. The first method that

was able to ionize high-molecular mass molecules such as proteins was achieved using plasma desorption (PD) ionization in 1982 (34), based on an earlier method described by Macfarlane and co-workers (35).

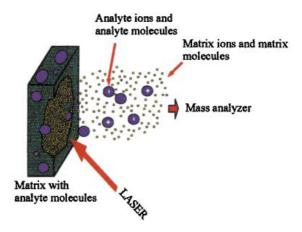

It is however only with the inventions of the electrospray ionization (ESI) and the matrixassisted laser desorption/ionization (MALDI) technique that peptides and proteins became really amenable to mass spectrometry analysis. In the eighties Fenn and co-workers (Yamashita & Fenn, 1984) developed electrospray ionization as a technique to ionize intact large molecules in solution. One of the peculiarities of ESI is to generate ions of differing charge states for the same analyte leading to spectra with numerous peaks. The nature of ESI has the advantage of being directly compatible with liquid chromatography and capillary electrophoresis systems so that peptides or proteins mixtures analyzed by one of those two methods can be investigated online by ESI-MS. During the same period Karas and Hillenkamp (36) discovered matrix assisted laser desorption/ionization (MALDI). Tanaka was able to obtain protein molecular ions of masses up to typically 25000 Da with a matrix made of an ultra fine metal powder mixed with glycerol (37) when Karas and Hillenkamp were investigating the polypeptide mellitin, 2843 Da, and the oligosaccharide stachyose, 666 Da. It is however the type of matrix that Karas and Hillenkamp used, a UV-light absorbing organic compound, that is the basis for most of the now existing MALDI applications (38).

#### **1.4.2 Ionization technique**

Matrix-assisted laser desorption/ionization (MALDI) and Electrospray ionization (ESI) are nowadays the most commonly used ionization processes to analyze proteins and peptides by mass spectrometriy. Their principles and characteristics are described below.

#### 1.4.2.1 Matrix-assisted laser desorption/ionization (MALDI)

The generation of a protonated molecule in the gas phase using the MALDI ionization process is achieved by mixing the analyte of interest with a large excess of a matrix material and to let them co-crystallize onto a planar surface, typically a metallic target. The resulting crystal is then irradiated by nanosecond laser pulses, typically using a nitrogen laser at a wavelength of 337 nm or, more recently, solid-state Nd: YAG laser at a wavelength of 355 nm. The matrix plays a particular role in the MALDI process (Fig. 1.6). First, the matrix absorbs the incoming energy of the laser pulse (therefore protecting

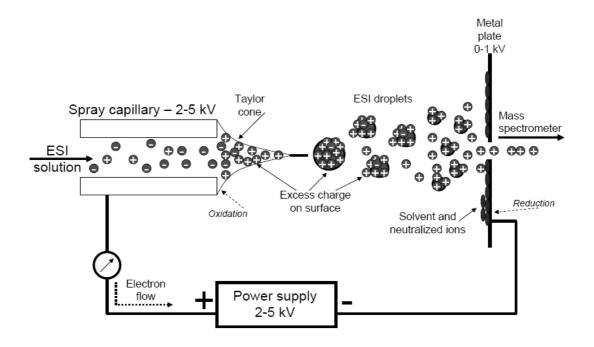

**Figure 1.6:** Schematic representation of MALDI process and instrument. A sample cocrystallized with the matrix is irradiated by a laser beam, leading to sublimation and ionization of peptides (Adapted from Mann et al., (39)).

the analyte from a direct "hit"), which is then followed by a thermal explosion leading to desorption of the analyte and subsequent ionization by charge transfer from the matrix to the analyte in the gas phase. Matrices are typically small organic molecules with an absorbance maximum matching the wavelength of the laser employed, but differing in the amount of energy they impart to the biomolecules during desorption and ionization and hence the degree of fragmentation (unimolecular decay) that they may cause. Thus, peptides are typically analyzed using so-called hot matrices such as  $\alpha$ -cyano-4-hydroxycinnamic acid or dihydrobenzoic acid while protein work would use "colder" matrices such as sinapinic acid. The MALDI ionization process is characterized by the formation of mostly singly-charged ions, therefore generating simple ion spectra, but putting a special requirement on mass analyzers to analyze the wide variety of ions (in respect to their m/z ratio) that can be generated.

The precise nature of the ionization process in MALDI still remains speculative in its nature and the obtainment of high signal intensities with good resolution is determined to some extent by trial and error, depending on incorporation of the analytes into crystals, their likelihood of capturing and/or retaining a proton during the desorption process and a number of other factors including suppression effects in peptide mixtures. Proteins generally undergo fragmentation to some extent during the MALDI process, resulting in broad peaks and loss in sensitivity; therefore MALDI is mostly applied to the analysis of peptides.

### 1.4.2.2 Electrospray ionization (ESI)

The electrospray ionization technique is performed using a liquid interface. A suitable solvent containing the analyte of interest is passed through a hypodermic needle set at high voltage to electrostatically disperse, or electrospray, small, micrometer-sized charged droplets, which rapidly evaporate and which impart their charge onto the analyte molecules (Fig. 1.7). The ionization process takes place at atmospheric pressure and is therefore very gentle (without fragmentation of analyte ions in the gas phase). The generated ionized molecules are transferred into the mass spectrometer with high efficiency for analysis. Depending of the flow rate (mid  $\mu$ l to ml/min), the electrospray process need to be assisted using nebulizer gas.

**Figure 1.7:** Overview of the mechanics of the electrospray ionization technique. The high voltage applied to the spray sample causes positive charge to build up at the spray tip. Due to the charge and the pressure a so-called Taylor cone is formed. From the Taylor the charged droplets well decrease in size and split, until eventually single proteins or peptides with multiple charged are desorbed and transferred to the mass spectrometer inlet (Adapted from Lottspeich and Zorbas(32)).

A wide range of compounds can be analyzed by ESI-MS; the only requirement is that the molecule should be sufficiently polar to allow attachment (in the positive ionization mode) or removal (in the negative ionization mode) of a charge. This includes proteins, oligonucleotides, sugars (with less sensitivity, as sodium rather than hydrogen is the charging agent), and polar lipids. For a given compound, the signal strength (peak height in the spectrum) increases linearly with the analyte concentration over a wide range until saturation occurs. Similarly, very low flow rate (below the  $\mu$ l/min range) also favor high sensitivity as

the inner diameter of the electrospray needle can be reduced to produce smaller droplets with enhanced ionization potential for the analyte.

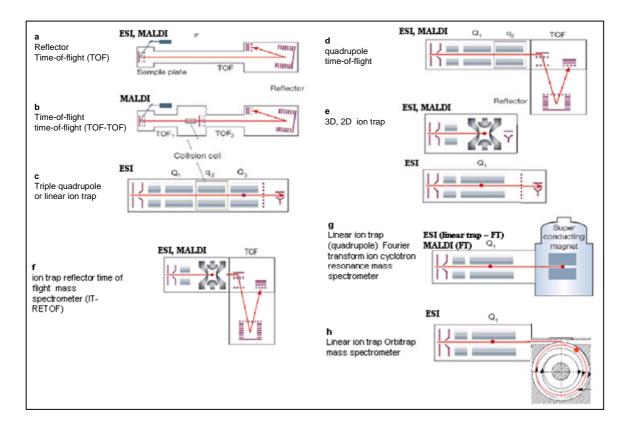

There does not seem to be an upper mass limit for analysis by ESI-MS. Large ions are typically multiply charged (proteins and peptides by added protons in the positive mode and abstracted protons in the negative mode), which brings them into the mass-to-charge (m/z) measurement range of most mass analyzers. The distribution of charges for an analyte gives rise to the typical multiple charge envelop. The resulting spectrum can then be simplified by deconvolution, an algorithm that sums up the signal intensity into a single peak at the molecular weight of the analyte. Very complex mixtures can be analyzed by ESI-MS, but spectra become increasingly difficult to interpret as the molecular weight of the components and their number increases.

Electrospray can be performed either in infusion mode, the so-called nanoelectrospray format, or in combination with a liquid separating technique, such as high-performance liquid chromatography. When these two techniques are coupled in the so-called LC-MS configuration, the eluting components of the sample can be analyzed online by the mass spectrometer. In this scenario, sample cleanup, separation, and concentration are all achieved in a single step.

# 1.4.3 The Mass Analyzer

The mass analyzer is the part of the mass spectrometer in which ions of given m/z ratio can be separated from each other, therefore conferring to the mass spectrometer its analytical power. In the field of proteomics, critical parameters are mass accuracy, sensitivity, resolution, and the ability to generate fragment spectra (tandem MS) informative enough to infer the identity of the parent ion.

MALDI and ESI ionization technique have been typically coupled to five types of mass analyzers: the ion trap, the time-of-flight (TOF), the quadrupole, the Fourier transform ion cyclotron (FT-MS) and the electrostatic ion trap (Orbitrap) analyzers. All these analyzers present different characteristics and performance profiles; most of them can be used either stand-alone or in combination with additional analyzers, either to combine the analytical strengths of two complementary ion selection strategies or to perform structural analysis of molecules by using successive ion selection processes. A summary of the most common mass analyzer configurations used in the proteomic field is shown in Fig. 1.8.

**Figure 1.8:** *Instrumental configurations of the commonly used mass spectrometers in proteomics. The typical ionization technique that is used for each of those mass spectrometers is indicated (Adapted from Aebersold, R and Mann, M. (40)).* 

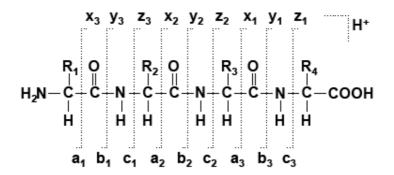

All ion trap mass analyzers share the ability to store ions for a certain time before ejecting them sequentially to a detector or to another mass analyzer. Their trapping capability make them very sensitive; however, only a limited number of ions can be accumulated at their point-like centre before space-charging distorts their distribution, which results in relatively low mass accuracy. The 'linear' or 'two-dimensional ion trap' (41) is a recent development where ions are stored in a cylindrical volume that is considerably larger than that of the traditional, three-dimensional ion traps. Linear ion traps can be operated either as a quadrupole (continuous) or as an ion trap (pulsed) analyzer, allowing increased sensitivity (1-2 times), higher trapping capacity (40 times) and trapping efficiency (11-14 times) than conventional 3D traps. The FT-MS and the Orbitrap mass analyzers are also ion trapping instruments but they capture ions under high vacuum in a high magnetic or electrostatic field respectively, which enables exquisite mass accuracy, high resolution, and dynamic range. In their commercial versions, however, these two mass analyzers have been used as ion detectors and have been coupled with other types of analyzers, such as a linear ion trap or a quadrupole, for ion isolation and selection.

Time-of-Flight (TOF) mass analyzers are one of the simplest separating devices in the mass spectrometric field. Incoming ions are accelerated to high kinetic energy and are separated along a flight tube as a result of their different velocities before being detected. In a more complex configuration, the so-called "reflector time of flight" (reTOF) mass analyzer, incoming ions are turned around in a reflector (an electrostatic mirror) which compensates for slight differences in kinetic energy which might otherwise severely limit the resolution obtained by such mass analyzers.

Quadrupole are versatile mass analyzers that can be used either as focusing lens (all ions go through at any time), as a time-dependent ion scanning device (ions of a given m/z ration are transmitted one after the other), or as a static mass filter (only ions of a given m/z ratio can be transmitted at any time). Quadrupole's selectivity relies on an electric field of various intensity rotating between four hyperbolic rods, allowing a stable trajectory only for ions of a particular desired m/z range. While quadrupole-based mass spectrometers used to be quite common a decade ago, the analyzer's rather low resolution has limited them to special mass spectrometric applications, such as quantification by multiple-reaction monitoring, or in combination with other mass analyzers, such as in the hybrid quadrupole-Time-of-Flight (Q-TOF) mass spectrometer.

Structural information of peptides is typically gained by collision-induced dissociation using tandem mass spectrometers. In this technique, an ion of interest is selected in the first mass spectrometer and is then dissociated by collision with an inert gas, such as argon or nitrogen, in a collision cell. The resulting fragments are then transmitted to the second mass spectrometer, producing the tandem mass, or MS/MS, spectrum. In most instruments in use today, multiple collisions impart energy onto the molecule until it fragments. (This is lowenergy fragmentation, in which any single hit is not sufficient to break a peptide bond. In high-energy fragmentation, the molecules have higher velocity and a single hit can break bonds). The most common ion types produced in the low-energy fragmentation mode are b and y ions, after fragmentation of the amide bond with charge retention on the N or C terminus, respectively (Fig. 1.9). Several of the mass spectrometers depicted in Fig. 1.8 are suitable for tandem mass spectrometry. For example, a TOF-TOF instrument (Fig. 1.8, panel b) includes a collision cell between two TOF sections. Ions of a given mass-to-charge (m/z)ratio are selected in the first TOF section, fragmented in the collision cell, and the masses of the fragments are separated in the second TOF section. In triple-quadrupole instruments, (Fig. 1.8, panel c), ions of a particular m/z are selected in a first section (Q1), fragmented in a collision cell (q2), and the fragments are separated in Q3. The quadrupole TOF hybrid

instrument combines the front part of a triple quadruple instrument with a reflector TOF section for measuring the mass of the product ions. This instrument combines the versatility

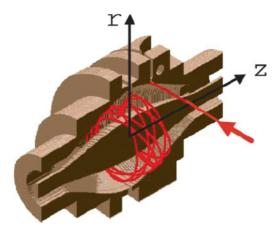

**Figure 1.9:** *Product ions generated in the fragmentation of peptide molecules by tandem mass spectrometry. Collision-activated dissociation (CID) causes single cleavage to occur more or less randomly at the various amide bonds in the collection of peptide molecules. This process generates a series of fragments that differ by a single amino acid residue. Ions of type y contain the C terminus plus one or more additional residues. Ions of type b contain the N terminus plus one or more additional residues. Additional ion types such as a, c and x and z types correspond to cleavages at different positions in the backbone (Adapted from Lottspeich and Zorbas (32)).* 

of a triple quadrupole instruments with the mass accuracy and resolution expected from a TOF analyzer. Finally, ion traps (Fig. 1.8, panels e, g, h) represent a special type of tandem mass spectrometer as ion traps can be operated both as a trapping device and a collision cell. Ions of interest with specific m/z ratio are first accumulated in the trap and then excited by resonance. The resulting fragments ions are trapped again in the ion trap analyzer until they are sequentially ejected from the trap for detection.

# 1.4.3.1 The Linear Ion Trap-Orbitrap Mass Spectrometer

The ever increasing demands in mass accuracy and resolution from research areas such as proteomics and metabolomics have stimulated the development of novel types of mass spectrometers combining high performance with moderate size at an affordable price. The Orbitrap-based mass spectrometer, manufactured by Thermo Electron (now Thermo Fischer Scientific) based on the invention of Makarov (42, 43), is the first novel mass analyzer introduced in the market in decades.

The Orbitrap can be considered as a modified Kingdom trap or, more simply, as a modified form of a quadrupole ion trap using static electrostatic fields while the quadrupole ion trap uses a dynamic electric field (44). A cross-view of the Orbitrap mass analyzer is shown in Fig. 1.10.

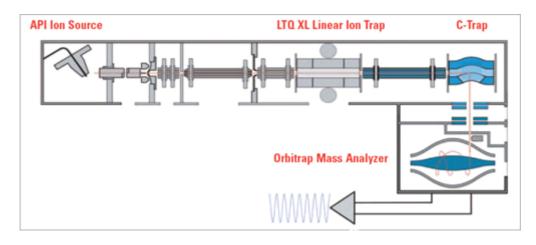

**Figure 1.10:** Cross-view of the Orbitrap mass analyzer. Ions are injected into the Orbitrap at the point indicated by the red arrow. The ions are injected with a velocity perpendicular to the long axis of the Orbitrap (the z-axis). Injection at a point displaced from z=0 gives the ions potential energy in the z-direction. Ion injection at this point on the z-potential is analogous to pulling back a pendulum bob and then releasing it to oscillate. Figure adapted from Hu et al., (45).

Ions injected into the Orbitrap mass analyzer assume a circular movement in the trap due to the electrostatical field. The specially shaped electrodes produce an electrostatic potential containing no cross-terms in *r* and *z* so that, when ions are injected at a point displaced from z=0, the resulting potential in the *z*-direction is exclusively quadratic. Ion motion along the *z*-axis may be described as an harmonic oscillator and is completely independent of *r*,  $\varphi$  motion ( $\varphi$  is the angular coordinate). Therefore, an ion mass/charge ratio *m/z* is simply related to the frequency of ion oscillation  $\omega$  along the *z*-axis (Eq. 1)

$$\omega = \sqrt{(z/m) \cdot k} \tag{1}$$

The main components of the commercially-available LTQ-Orbitrap hybrid mass spectrometer (Thermo Electron) are illustrated in the figure 1.11 (see also Hu et al. 2005 for a detailed description of the first orbitrap prototype). An electrospray source creates ions, which are transferred using RF-only guide quadrupoles and octapoles into a a linear quadrupole ion trap. The ion guide brings the ions through several stages of differential pumping, from the atmospheric pressure of the ion source to approximately 10<sup>-5</sup> Torr in the LTQ ion trap. The LTQ ion trap is required to couple the continuous electrospray ion source with the Orbitrap, which operates in a pulsed fashion. After a sufficient number of ions has been accumulated (typically taking 10–400 ms), the back lens of the linear ion trap is pulsed open and ions are collected in a C-shaped ion trap, which is used to store and collisionally cool ions before injection into the orbitral trap as defined ion packets with very small temporal (100–200 ns)

**Figure 1.11:** The commercially-available LTQ-Orbitrap mass spectrometer. Ions are produced by the electrospray ion source and then proceed through the source, the focusing lenses and octapoles to pass into the linear ion trap (LTQ). The LTQ mass analyzer can be used either as a stand-alone instrument, submitting ions to MS and MSn analysis, or it can serve as an ion accumulator and buncher, allowing the pulsed Orbitrap mass analyzer to be coupled to the continuous electrospray ionization source. After accumulation of a sufficient number of ions, they are axially ejected from the LTQ and collected in a C-shaped ion trap (C-Trap) from which they are passed into the Orbitrap mass analyzer. The trapped ions assume circular trajectories around the center electrode and their axial oscillations, along the center electrode, are detected and transformed back to mass spectrum using fast Fourrier Transform (Figure downloaded from the Thermo Fisher web site (<u>http://www.thermo.com/</u>) on July 19, 2008.

and spatial spread. Once injected into the Orbitrap at a position offset from its equator, ion bunches start coherent axial oscillations without the need for any additional excitation. All ions have exactly the same amplitude, although ion packets of different mass/charge ratios will execute their axial oscillations at their respective frequencies. The exquisite resolution attained in the orbitrap mass analyzer is only possible if the ion packet remains spatially coherent during the analysis time (up to several seconds); beside superior manufacturing, the performance of the instrument is made possible by keeping the orbitrap analyzer at very high vacuum, approximately  $10^{-10}$  Torr. The detection of an ion image current due to motion along the Orbitrap axis is made possible by splitting the outer electrode in half at *z*=0. The ion current is differentially amplified from each half of the outer electrode and then undergoes analog-to-digital conversion before processing by customized control and acquisition software. The so-called resulting transient is the converted back to a mass spectrum using fast Fourrier transform.

The superior performance of the LTQ-Orbitrap mass spectrometer was critical to carry on the protein identification of the BBM membrane and to enable the initial steps aiming at developing a label free quantification approach based on LC-MS/MS data. This instrument's high mass accuracy (1-3 ppm), excellent resolution (up to 100,000 depending on the

acquisition time) and extended dynamic range (more than 3 orders of magnitude) made the Orbitrap the ideal analytical tool for this study.

# **1.5 Data analysis and Bioinformatics tools**

The analysis of the large amount of data generated in mass spectrometry-based experiments is a significant challenge and is currently a bottleneck in many proteomics approaches. Nevertheless, a significant progress has been made in the form of software package for proteome analysis and their application to biological and clinical research.

The vast majority of proteomic data nowadays are being generated by mass spectrometry, more specifically, by tandem mass spectrometers of ever increasing performance. These instruments and the diverse workflows they support have in common that they generate hundreds to tens of thousands of fragment ion spectra per hour of data acquisition. The assignment of these fragment ion spectra to peptide sequences, the inference of the proteins represented by the identified peptides and the determination of their abundances in the analyzed sample present complex computational and statistical challenges. It is essential for proteomics to develop and generally apply tools and solutions to these problems to provide accurate and reproducible results.

# **1.5.1 Protein Identification**

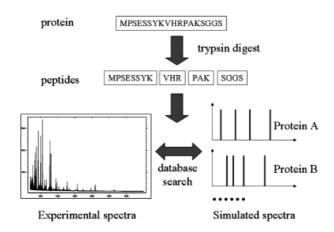

The protein identification process follows a well-defined analytical scheme requiring the consideration of several parameters to return a successful and unambiguous answer. Not surprisingly, the type of sample preparation, choice of instrument, data acquisition and peak peaking parameters define which computational identification process can be selected and the scope of results that can be obtained.

All protein identification algorithms used in high-throughput mass spectrometry-based proteomics experiments share in common the characteristic to compare an experimentally recorded mass spectrum with the protein/peptide information derived from a sequence database. The quality and the significance of the match are then provided back to the user in the form of more-or-less elaborate statistics, a topic which has seen many progresses recently. A few years ago, the experience of the mass spectrometer's operator was often determinant to define at which thresholds a protein or a peptide hit was relevant in an experiment. The development of probabilistic approaches to rank the likeliness of protein/peptide identification and the use of decoy databases to estimate the false positive identification rate has been determinant to define generally applicable rules to protein identification.

There are two strategies commonly used for high-throughput protein identification based on mass spectrometry, the Peptide Mass Fingerprint (PMF) and Fragmentation Mass Fingerprinting (FMF).

## **1.5.1.1 Peptide Mass Fingerprint (PMF method)**

Peptide mass fingerprinting (PMF) was the first available method for large-scale protein identification using mass spectrometry, and is still widely used (46, 47). This strategy compares the signals observed in a MS analysis with theoretical spectra obtained from an *in silico* digestion of each protein sequence from a reference database (Fig. 1.12). One of the main limitations of the PMF method consists in the basic assumption of the algorithm that the signals in the experimental spectrum must originate from one or from very few proteins, making this approach incompatible with the identification of proteins in complex mixtures. As a result, protein identification using PMF has been mostly carried out in proteomic approaches based on 2D gel electrophoresis, for fractionation of a biological sample, combined with MALDI TOF MS analysis of the usually rather pure 2D gel spots.

**Figure 1.12:** *PMF protein identification scheme*. The protein in the sample is digested into peptides, whose mass-to-charge ratios are shown in the PMF spectra. The PMF spectra are compared with the simulated spectra of the in silico-digested proteins. Figure adapted from Song, Z. et al., (48).

Used with the proper data, PMF remains popular and works well in practice because of its speed to compute PMF scores against a database. PMF yields in many cases protein identifications with high confidence, especially with organisms with smaller genomes. Interestingly, a confident PMF identification score can usually be obtained even in the presence of point mutations or occasional post-translational or chemical modifications, as long as a minimal number of peptides characteristic for a protein remains detectable in the spectrum. A non-confident identification score may pinpoint to splice variants, individual

sequence variants and errors in the database, or more prosaically, to the presence of a protein mixture in the sample or to incomplete digestion. As more sophisticated methods for scoring PMF are being developed, more proteins may now be identified with confidence (49).

Another limitation of the PMF strategy is its sensitivity to database size. There is a direct correlation between the statistical confidence a PMF algorithm can ascribe to protein identification and the size of a sequence database. A larger database has an elevated chance of experimental masses randomly matching theoretical peptide masses in these databases, thereby decreasing the confidence of protein identifications using PMF. The same observation is also valid if mass spectra are searched against a database using very relaxed search criteria (for example, by relaxing the enzymatic specificity a peptide has to display for being considered in the search, or by increasing the error by which theoretical masses are allowed to match experimentally-determined peptide masses) or if many dynamic modifications are considered simultaneously (oxidation, phosphorylation, etc., which increase the actual size of the search database).

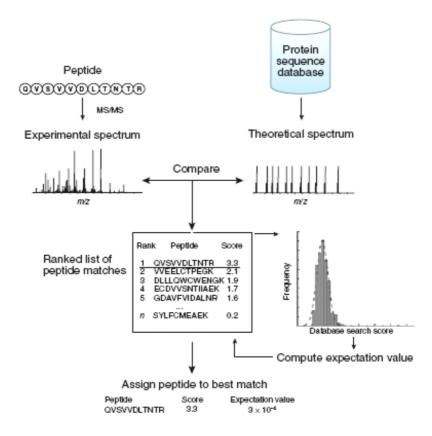

Popular search engines to mine PMF data include Mascot, MS-Fit and ProFound. All these tools allow the user to set up their searching parameters, such as for example database choice, constant and variable modifications, mass accuracy error, and miss cleavages. Each engine returns the result of the search with a measure of confidence gauging how significant is the obtained identification. For example, Mascot (50) uses a proprietary algorithm based on the MOWSE scoring system (47). By calculating the distribution of peptide lengths across the entire search database, a probability can be calculated for each observed peak for this match being purely random. While, most of the time, all PMF search engines returns similar answers, it is also not uncommon that multiple search of PMF data by using different tools leads to different identifications because of the different scoring systems that each of these tools use.

## 1.5.1.2 Fragmentation Mass Fingerprinting (FMF)

The currency of information for tandem mass spectrometry-based proteomics is the fragment ion spectrum (MS/MS spectrum) of a specific peptide ion that was fragmented, typically, in the collision cell of a tandem mass spectrometer. The correct assignment of such a spectrum to a peptide sequence is a first and central step in proteomic data processing. A large number of computational approaches and software tools have been developed to automatically assign peptide sequences to fragment ion spectra. These can be classified into three categories: (i) Fragmentation Mass Fingerprinting (FMF), by correlating un-interpreted fragment ion spectra with theoretical spectra predicted for each peptide contained in a protein sequences database, or by correlating acquired fragment ion spectra with libraries of experimental MS/MS spectra identified in previous experiments (spectral library searching); (ii) De novo sequencing, where peptide sequences are explicitly read out directly from fragment ion spectra; and (iii) hybrid approaches, such as those based on the extraction of short sequence tags of 3–5 residues in length, followed by 'error-tolerant' database searching.

The FMF strategy is to date the most frequently used peptide identification method for largescale proteomics studies; it was also used in this study and, for that reason, it will be described in more details in the following paragraph.

Several MS/MS database search engines have been developed to support the FMF approach and their basic functionality is illustrated in the Fig. 1.13. Mascot and Sequest are the most commonly used programs for peptide identification using the FMF strategy. Mascot is based on the probabilistic MOWSE algorithm which uses the parent mass and the relative abundance of the derived fragment masses for that parent as constraints on the search space. The Sequest peptide identification process starts with the selection of candidate sequences based on the length of a continuous y/b fragment ions correlating with the input spectrum. A second, more sensitive and more computational-intensive correlation function returns scores based on the presence of significant peaks in the experimental spectrum corresponding to the expected y/b ion peaks in each theoretical spectrum in the database. Sequest outputs a ranked list of candidate peptide identifications.

**Figure 1.13:** *Peptide identification by MS/MS database searching.* An acquired MS/MS spectrum is correlated against theoretical spectra constructed for each database peptide that satisfies a certain set of database search parameters specified by the user. A scoring scheme is used to measure the degree of similarity between the spectra. Candidate peptides are ranked according to the computed search score, and the highest scoring peptide sequence is selected for further analysis. The figure was adapted from Nesvizhskii et al., (51).

Regardless of the search engine used, the fraction of spectra identified is usually quite low, with 10–20% being typical, although some high-quality experiments may yield as high as 50% identification rates. This is largely dependent on the quality of the sample, the type of mass spectrometer used, and the manner the mass spectrometer has been set up.

One of the main weaknesses of this identification strategy is that a top-scoring peptide, as determined by the search engines, may not necessarily be the correct candidate. The remaining challenge is to determine whether the putative identifications are in fact correct. Five years ago, a standard procedure might have been to apply an arbitrary cutoff score and to manually inspect spectra and judge correctness. This was extremely labor intensive and subjective, thus not reproducible. Recently several computational strategies have emerged for validating the search results and assigning a false discovery rate at the peptide level for a given threshold. One of those strategies is to repeat the identification search using a reverse or a shifted database by applying the same searching criteria, thus allowing the estimation of a

false discovery rate for a given experiment (52). An alternate strategy consists of storing MS/MS data in a library at an early stage of the identification process. Comparison of MS/MS data occurs by comparing experimental spectra with those previously measured and stored in a database using a spectra-matching algorithm. Such an approach was proven to be very effective in the small molecule area (53).

# 1.5.2 Validation of peptide and protein identification

The purpose of most proteomic experiments is not the identification of peptides, but the identification of the proteins present in the sample before digestion. Thus, the peptide sequences which were identified from the fragment ion spectra need to be grouped accordingly to their corresponding protein, and a confidence measure needs to be recomputed at the level of proteins. This process is by far not straightforward owing to several challenges, and it has not been satisfactorily resolved up to today. First, many correctly identified peptides tend to cluster into a relatively small number of proteins, especially when there were very abundant proteins in the analyzed sample. At the same time, incorrect spectral identifications match randomly to a much larger number of proteins in the searched sequence database. Thus, almost every high scoring, incorrect spectral assignment introduces one additional incorrect protein identification, resulting in a significant increase in the false discovery rate when going from the peptide to the protein level. Second, an important number of peptides are not unique to a single protein and hence will point to more than a single entry in the protein sequence database. Such cases most often are the result of the presence of homologous proteins, splicing variants, or redundant entries in the sequence database. This problem is particularly serious in the case of higher eukaryotes, or when protein sequence databases are derived from genomic databases. Therefore it becomes critical to have an appropriate tool that is able to assess the validity of the protein inference and associate a probability to it. A tool such as ProteinProphet combines probabilities assigned to peptides identified by MS/MS to compute accurate probabilities for the proteins present (54).

In order to increase the confidence level for peptide or protein identification, technical replicates of an analyzed sample might be necessary. In an LC-MS/MS proteomic approach, unique peptide coordinates (such as retention time and accurate mass) could be useful for validating identification.

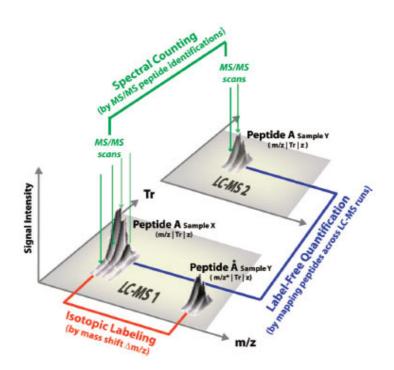

Another method to confirm the presence of a protein via the characterization of one (or several) of its constitutive peptides is to use Multiple Reaction Monitoring (MRM). In the MRM-targeted strategy, which is typically performed the same way as for a quantification

experiment (see section 1.6.2), one sets the mass spectrometer to specifically detect signature ions of the peptide of interest, usually in presence of its isotopically labeled counterpart to pinpoint the exact retention time in the analysis and to validate the chosen transitions. Performed on a triple quadrupole instrument (or hybrid quadrupole/linear ion trap instrument), the data acquired by setting both mass analyzers to predefined m/z values achieve increased selectivity while the non-scanning nature of this experiment accounts for an increased sensitivity. It thus allows detection and structural confirmation of low abundance analytes in complex biological samples.

# **1.6 Quantification in Proteomics**

The determination of the relative levels of protein abundance in organisms or tissues exposed to different physiological or environmental conditions is essential to the study of disease processes and cellular responses to stress. Until recently, a quantitative proteomics experiment would have typically been performed by differential display analysis using two-dimensional gel electrophoresis (2DE), whereas protein spot intensities on associated gels would have been compared and the differences quantified. While this method compares favorably to the precision achieved by modern mass spectrometers in terms of sensitivity and reproducibility (especially in the DIfferential Gel Electrophoresis [DIGE] strategy pioneered by Amersham BioSciences, today GE Healthcare), its dependence on the two-dimensional gel electrophoresis platform limits its applicability and throughput, especially when fractionation is required. In the last few years, especially with the popularization of high-performance mass spectrometers around laboratories, several alternative strategies have been proposed for relative quantification via mass spectrometry (55).

In this section three conceptually different strategies to perform quantitative LC-MS experiments will be presented and are summarized in the Fig. 1.14. In the first approach, quantification is achieved by spectral counting of fragment ion spectra assigned to a particular peptide; in the second approach, quantification is achieved by the differential detection of peptides or proteins compared to an internal standard in the form of their isotopically-labeled counterpart; and in the third approach, peptides and proteins are quantified "label-free" (that is, without internal standard) based on the precursor ion signal intensities.

**Figure 1.14:** *Representation of LC-MS based quantification strategies in proteomics.* In the first approach, spectral counting estimates abundance values based on the number of times a peptide was successfully identified by tandem mass spectrometry (MS/MS) and compare these across experiments (green). In the second approach using isotopic labeling, quantification is based on the differential analysis of two samples, X and Y, in the same LC-MS run whereas the peptide A (in sample X) and its stable isotope labeled counterpart  $A^*$  (in sample Y) are detected by their characteristic mass difference  $\Delta m/z$  (red). In the third approach using label-free quantification, peptide signals are extracted by tracking the isotopic patterns along their chromatographic elution profile. Relative quantification between the LC-MS run 1 and the LC-MS run 2 is achieved by comparing the coordinates m/z, Tr and z of the peptide (blue). This picture is adapted from Mueller et al., (56).

# 1.6.1 Semi-quantitative analysis based on Spectral Counting

This type of analysis was originally developed to evaluate semi-quantitatively shotgun proteomic approaches. In this strategy, wherein the main goal of the experiment is to identify a maximum number of peptides per LC-MS run, the mass spectrometer is set up to automatically select a number of peptide precursor ions from the full scan MS for collision induced dissociation (CID) analysis according to predefined criteria (typically the 1-5 most intense precursor ions of every full scan is selected for MS/MS analysis). The quantification strategy is based on the number of times a precursor ion peptide is selected for fragmentation and identified in a large data set. This value is related to the abundance of a peptide represented by its precursor ion in the sample mixture. Spectral counts of peptides associated with a protein are then averaged into protein abundance index (57-60).

Spectral counting approaches have most frequently been used for the analysis of low to moderate mass resolution LC-MS data as a convenient, fast, and intuitive quantification strategy. A draw back in this type of approach is its dependency on the quality of MS/MS peptide identification, because errors in the assignment of peptides propagate directly into protein abundance indexes. The assembly of spectral counts of peptides into a protein index is unproblematic for peptides whose sequences belong to only one protein; however, it is difficult to resolve protein for which peptides map to multiple protein sequences (as, for example, for peptides from conserved protein regions). It has been suggested, therefore, that spectral counting ought to be used only with proteotypic peptides (61).

Another hurdle with spectral counting is the manner spectral counts are computed if only a small number of peptide identifications have been achieved for a given protein. This situation can occur, for example, for proteins of low abundance (only a few representative peptides might be detected), for proteins of low molecular mass or with specific physicochemical characteristics that limit peptide observability (these proteins might generate only a few representative peptides for LC-MS/MS measurements), if peptide identification becomes ambiguous or if the sample complexity overwhelms the mass spectrometer's dynamic range. As a result, the spectral counting quantification method should be used for high abundant proteins, based on a large number of peptide identifications. It becomes unreliable for proteins with one- to two-peptides identifications since low-abundance peptide identification is not reproducible between different LC-MS runs (precursor masses selection for MS/MS is skewed towards peptides of high abundance.

In a modified quantification approach, peptide abundance can also be estimated from the extracted ion chromatograms (XIC), which, in this way, partially alleviate the MS/MS problem (62). In this approach, it is sufficient that a peptide has been successfully analyzed by MS/MS in at least one of all the LC-MS runs. The mass to charge ratio m/z and the retention time  $T_R$  of the MS/MS of the precursor ion are then used for the extraction of the XIC of this peptide in the other LC-MS measurements. In this case, however, any fluctuation on the LC system will cause a drift on the retention time of the peptide (see also section 1.6.3).

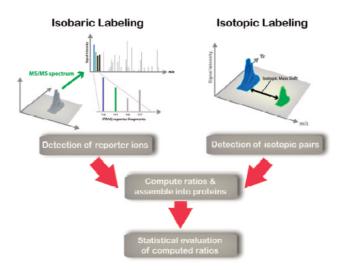

In summary, quantification approaches based on spectral counting or on the extracted ion chromatograms of an assigned peptide represent valuable techniques for LC-MS/MS data of low- and medium-resolution. This strategy is not recommended for underrepresented peptides as the MS/MS analytical strategy is biased for high abundant peptides in a mixture.

# 1.6.2 Relative Quantification based on Differential Stable Isotope labeling

Differential stable isotope labeling in combination with mass spectrometry has become an extremely popular method for quantitative proteomics (40). Absolute quantification has been

demonstrated whereas the peptides of a sample are compared against their spiked-in isotopic labeled synthetic analogues (63). Differential isotopic labeling also allows the relative quantification of peptide intensity between multiple biological samples within a single LC-MS measurement.

A variety of MS-compatible labeling techniques are now available. They can be roughly divided into two categories, isobaric or isotopic labeling strategies. Fig. 1.15 illustrates the workflow of these two approaches.

**Figure 1.15:** Schematic representation of the quantitation principles of isobaric and isotopic labeling. Isobaric labeling generates in the MS/MS different reporter ions that are used to calculate peptide abundance between different samples. On Isotopic approaches differentially label peptides or proteins from two samples (green / blue) produce isotopic pairs of characteristic mass shifts. Common to both approaches are the next steps where peptide ratios are computed, assembled into protein ratios and then statistically assessed to evaluate the significance of the detected fold changes. Figure is adapted from Mueller et al.,(56).

Isobaric labeling reagents, as exemplified by the iTRAQ reagents (64), are peptide tags that introduce an identical mass shift to all derivatized peptides (that is, these peptides are undistinguishable in the MS spectrum), but produce MS/MS-specific reporter ions that are used for quantification. Differentially labeled samples are combined and simultaneously analyzed by shotgun LC-MS/MS analysis, and peptide abundance values are compared via the reporter fragments in the MS/MS spectra. In contrast, isotopic labeling methods, for example the ICAT reagents (65) and the SILAC protein labeling strategy (66), generate pairs of peptides with characteristic mass differences introduced by the applied label. Typically, the isotopic forms of an MS/MS identified peptide are detected by their mass shifts and identical elution profiles and are used to compute a peptide abundance ratio between the "heavy"

labeled peptide from one condition and the "light" peptide version of the other condition (Figure 1.14, blue and green coloring).

**Isobaric Labeling of Peptides** can be achieved, for example, with the new 8-plex iTRAQ labeling reagent that allows the simultaneous quantification of up to eight biological samples (Choe et al., 2007). The isobaric reagent reacts with primary amino groups and produces in the MS/MS fragmentation spectrum eight different unique reporter groups, one per reagent flavor, at 113, 114, 115, 116, 117, 118, 119, and 121 m/z. iTRAQ labeling does not increase the sample complexity at the MS level because the reagent is based and relies on a fully MS/MS-dependent workflow. Therefore, the strength of the approach, and its limitation, is that only peptides subjected to CID fragmentation which could be successfully assigned to a peptide sequence are quantified.

The Isotopic Labeling Techniques commonly used in proteomics for relative quantification experiments can be divided into three general categories: chemical tagging of peptides and proteins, stable isotope labeling of peptides during enzymatic digestion, and metabolic labeling of living cells and animals.

The first strategy using chemical tagging of specific amino acids is the Isotope Coded Affinity Tag (ICAT) method. In this technique, two biological samples are labeled at the peptide or protein level using chemically identical but isotopic different reagents specifically targeting cysteine groups. The labeled peptides differ in their molecular weight by 8 mass units (the newer ICAT reagents now introduces 9 mass units). After the labeling step, the samples are combined and subjected to mass spectrometric analysis. In the following years, a number of related strategies have been developed in which the sets of reagents differ in specificity, structure, mass difference, and number of isotopic forms (67). All these labeling techniques have in common that they generate a complex sample mixture consisting of pairs of chemically identical peptides of different mass. Those pairs are then detected in the precursor ion mass spectrum, and the signal intensity is used to compute the relative abundance of the respective analyte in either sample.

The incorporation of isotopic analogues as replacement of atomic elements in the peptide sequence can be done through enzymatic reaction. <sup>18</sup>O labeling is based on the incorporation of heavy oxygen into the C-termini of peptides during tryptic digestion of proteins in presence of heavy water (68). The major advantage of <sup>18</sup>O labeling is that the method is not limited to a specific subpopulation of peptides. This method is generic and can be applied in any kind of peptide sequence. However the optimization of the tryptic digestion process can be quite

difficult and the <sup>18</sup>O incorporation may not be very specific for the C-termini as other amino acids might be labeled, making data analysis more complex.

Metabolic labeling has become very popular since the development of the SILAC approach. In its original version, cell cultures are grown in media containing either light <sup>12</sup>C- or heavy <sup>13</sup>C-labeled arginine and lysine that are then metabolically incorporated into proteins through the cell cycle. After mixing the two samples and digestion, the generated isotopic peptide pairs are detected by mass shifts of multitudes of 6 mass units for each lysine or arginine incorporated. Since the label is added at a very early stage of the experiment, this technology allows normalizing for experimental variations introduced in the sample processing steps. The main limitation of the SILAC labeling strategy is that is largely restricted to biological material grown in culture, as is metabolic labeling of tissues by <sup>15</sup>N (a popular method to isotopic label bacteria (69, 70)), and thus is not generally applicable to tissues, body fluids, or clinical applications. A promising, but rather expensive approach for <sup>15</sup>N labeling of all the amino acids with high level of incorporation in mammalian (non human!) organisms has been suggested by (71). In this approach, a young (typically a newborn or a fetus) animal is fed for several weeks a special diet in which the nitrogen source is isotopic labeled, resulting in high rates of labeling in organs.

Multiple Reaction Monitoring (MRM) represents a MS-based quantification approach that is taking fully advantage of the labeling strategies mentioned above. MRM experiments differ from conventional proteomics approaches in that they are hypothesis-driven (i.e. screening for known or putative entities). As a part of this targeted approach proteotypic peptides (i.e. sequences that are unique to one single protein), and their corresponding fragmentation patterns are used to define MRM transitions. In such approaches, one starts by generating a list of proteins of interest, the corresponding proteotypic peptides are derived, and the associated fragment ions are predicted (or extracted from a database) to define the MRM transitions. Relative estimation of the elution times might also be made and all that information will then be used to generate a list of targeted peptides. Relative and absolute peptide quantification can be achieved by adding at some stage of the experiment the isotopic (not the isobaric!) labeled peptides and to measure all samples in presence of the same internal standards. As MRM is per se a multiplex methods (it has been claimed that several hundreds of peptides can be quantified in the same LC-MS experiment), it is thus possible to detect and quantify a large number of peptides in consecutive single LC/MS runs with minimal effort (72).

In summary, isotopic labeling strategies allow for the highly accurate quantification of LC-MS experiments since the differential analysis is performed on single LC-MS runs where the peptide pairs can be very accurately detected by the distinct mass shifts characteristic to the utilized labels. The described isotopic labeling strategies have in common that the combination of multiple, differentially labeled samples increases drastically the complexity of the peptide population. This is particularly problematic for the identification of peptide–ions by MS/MS where only a limited number of peptide signals can be subject to CID fragmentation during an LC-MS experiment. The selection of precursor ions is biased toward high-intensity peptide signals and leads to a prominent undersampling of low-abundance peptides. This limits the range of isotopic and, up to a certain point, isobaric labeling techniques since the computation of peptide/protein ratios is based exclusively on peptides that were successfully identified by MS/MS. Similarly, the chemical labeling strategies (for both the isotopic and the isobaric methods) increase intrinsically the variability of the experimental design because of the additional sample processing steps required by the procedure.

# 1.6.3 Label free quantitation of LC-MS data

Newer mass spectrometers with high scanning rates and high mass accuracy, such as the new generation of ESI-TOF, the LTQ-FT and the LTQ-Orbitrap instruments, have opened the way for the label-free quantification of LC-MS data. Typically, peptide signals are detected in the full MS scan and distinguished from chemical noise through their characteristic isotopic pattern. These patterns can then be tracked across the retention time dimension and used to reconstruct a chromatographic elution profile of the monoisotopic peptide mass. The total ion current of the peptide signal is then integrated and used as a quantitative measurement of the original peptide concentration (see Fig. 1.15). In principle, every peptide signal within the sensitivity range of the MS analyzer can be extracted and quantified independently of a MS/MS acquisition (73). This strategy increases the dynamic range for peptide detection and minimizes the bias against low-abundance peptides commonly observed for MS/MS-based approaches. Full MS measurements performed by the mass spectrometers of the latest generation provide very high resolution power and mass precision in the low parts per million range. Thus, the peptide signal extracted from the full MS level has become so precise and specific that the quantification process may now be uncoupled from the identification process.

In contrast to a differential labeling experiment, biological samples assessed in a label-free experiment are measured separately. The extracted peptide signals are then mapped across

multiple LC-MS measurements using the coordinates "mass to charge" (m/z) and retention time (Tr). A successful peptide tracking depends on the available mass resolution of the utilized mass spectrometer and the stability of the LC system. In this paradigm, the Tr reproducibility of each peptide across the LC-MS runs becomes critical and requires the use of bioinformatics tools for the correction of chromatographic fluctuations. High mass accuracy MS instruments in combination with sophisticated computational methods for signal intensity normalization offer a platform for the automated label-free quantification of complex biological mixtures in a linear dynamic range of 3 to 4 orders of magnitude without the requirement of MS/MS information.

Biological information is not directly inferred from a list of differentially-regulated masses and requires structural information, typically by tandem mass spectrometry. In a label-free experiment, even when performed on a modern mass spectrometer, typically only a fraction of the detected and quantified peptide features are identified by an MS/MS peptide assignment (74). Fig. 1.16 schematically represents some of the processes to follow the identification of peptides showing interesting quantitative patterns.

Peptide signals are extracted from the full MS (gray dots) and then tracked across LC-MS multiple measurements to generate a list of aligned peptides (red dots), which serves as a framework for further annotation efforts (75, 76). Each peptide signal is defined by its accurate mass and time tag (AMT) (77) on the mass and retention time dimension (blue flag), and a subset of these peptide elements are selected according to a specific property of the peptide signal (for example, here the intensity). These AMT tags are then subjected to post annotation where the identity of an AMT (i.e., protein name and peptide sequence) is derived by comparing its accurate mass and retention time coordinates to a map of AMT tags from successfully identified peptide signals (green flags). AMT tags can also be obtained from peptide identifications either in a targeted LC-MS/MS runs (inclusion list run) or in a large repository of MS/MS peptide identifications compiled from multiple LC-MS experiments (78) (MS/MS repository).

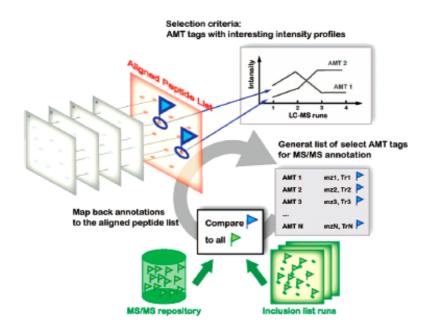

Figure 1.16: Schematic representation of post processing approaches to follow peptide characterization based on their accurate mass and retention time coordinates (AMT). An aligned peak list (red map) is generated by peak detection and alignment of multiple LC-MS runs (gray maps) AMT tags of peptide signals (blue flags) with interesting intensity profiles are then integrated into a list of AMT tags for annotation. Identities of AMT tags are derived from a map of identified peptides (green flags) by comparing AMT coordinates (mass and retention time) across LC-MS runs. These maps might be fed through a large repository of collected MS/MS peptide identifications or through targeted MS/MS via inclusion list runs. Figure is adapted from Mueller et al., (56).

In summary, label-free quantification represents a key technology for the analysis of complex biological samples due to its ability to exhaustively sample peptide signals detected directly at the full MS level. However, in order to be able to use this approach, there is a need for sophisticated computational methodology to process the acquired data.

In all the quantification approaches in order to be able to trust differential expressions of the quantified proteins it is very important to know what is the variability due to technical steps or biological replicates so that can be estimated what is significant different. Monitoring the technical variability and stability of the BBM preparation and the LC-MS system is part of this study, in order to develop the right tools and set the criteria that reflect what is common and what is different between the compared biological samples.

# **2. OBJECTIVES**

The primary goal of this study was the development and the evaluation of analytical strategies for the analysis and the identification of hydrophobic proteins by mass spectrometry. Analysis of membrane proteins in a complex mixture was always an obstacle for the proteomics field. Their hydrophobic nature requests a detergent for their solubilization and makes the use of traditional proteomics techniques less compatible (e.g. two-dimensional gel electrophoresis). Their low abundance in complex biological mixtures (in comparison to soluble proteins) requires additional purifications steps for their enrichment. Even at equal abundance, the identification rate of membrane proteins is lower than that of soluble proteins. This study aimed at better understanding constrains linked with the analysis of membrane proteins and at investigating possible improvements in this process.

The Brush Border Membrane (BBM) from mice small intestine was chosen as an ideal source of membrane proteins. The investigation of proteins that are located in the BBM membrane and may play a key role in cholesterol absorption has been of increasing interest in the recent years for many pharmaceutical companies because of the correlation of cholesterol absorption malfunction with cardiovascular diseases. This proteomic approach should confirm the findings of several studies that were based on gene analysis, activity tests and immunology assays, namely that the BBM contain proteins that participate in cholesterol regulation in the enterocytes.

A third goal of this study was to investigate conditions for which a quantitative mass spectrometric experiment using a label-free strategy could be used to investigate biological samples, as technical variability and sample stability of the BBM preparation were not known. The reproducibility of the technical steps has to be monitored for the whole workflow, from the BBM preparation until the mass spectrometric analysis of the samples, so to pinpoint difficulties and limitation of the workflow and preparing the way for a label free quantification strategy using only the information from the LC-MS data.

An additional aim of this study was to set the grounds for the analysis of gene expression along the small intestine of a mouse, in particular with the goal to compare gene expression of differentially treated mice or of mice with different genetic background.

# 3.2 Methods3.2.1 BBM Preparation

Brush Border Membrane (BBM) vesicles were isolated by using a modified protocol from Kessler et al. using calcium chloride precipitation (79). The small intestine (rinsed with PBS) or the scrapped mucosa thereof from wild type C57B/6J-Bom male mice (6-8 weeks old) was suspended in Homogenization buffer (50 mM Mannitol, 2 mM Tris, pH 7.1) in presence of protease inhibitor cocktail tablets (Complete, Roche) and 1 mM PMSF (from a 100 mM stock solution in ethanol). Each gram of tissue was suspended in 15 ml homogenization buffer. The suspension was homogenized four times 20 seconds using a Polytron (Kinemetica GmbH) at maximum speed with intervals of 40 seconds in ice. The homogenized tissue was then centrifuged at 3,000 x g for 15 min at 4 °C and the cell debris was discarded. The supernatant was re-centrifuged at 27,000 x g for 30 min at 4 °C. The resulting pellet was weighted and resuspended in Homogenization buffer (at the ratio of 1 gram of pellet in 15 ml Homogenization buffer) and CaCl<sub>2</sub> was added to a final concentration of 10 mM (from a stock solution of 1M CaCl<sub>2</sub> freshly prepared). After incubation on ice for 20 min, the 3,000 x g centrifugation step was repeated. The supernatant was then re-centrifuged at 27,000 x g for 30 min at 4 °C. The resulting pellet, which contained the BBM vesicles, was first washed twice with 1 M KCl, then twice with 0.1 M Na<sub>2</sub>CO<sub>3</sub>, with 30 min centrifugation at 50,000 g at 4 °C after each washing step. The purified BBM pellet was finally solubilised in storage buffer (100 mM Mannitol, 1 mM Heppes-Tris pH 7.5, 1% SDS and 1% CHAPS) in presence of protease inhibitor cocktail tablets Complete and 1 mM PMSF and stored at -80 °C.

The targeted inhibition of the His-Zn-dependent metalloproteases was achieved by adding 1 mM Amastatin (80, 81), 1 mM Angiotensin 1-5, and 1 mM Met-Bradykinin in all buffers and washing solutions. The excess of  $Ca^{+2}$  after the calcium precipitation step was removed with 40 mM EDTA at the first wash of the BBM fraction with KCl. (§ 4.1.2.3 figure 4.9: flow diagram of BBM preparation).

# 3.2.2 Protein concentration estimation by the BCA method

The BCA Protein assay is a detergent-compatible assay for the colorimetric detection and quantitation of total protein using bicinchroninic acid (BCA) as a reporting agent. The method combines the well known reduction of  $Cu^{+2}$  to  $Cu^{+1}$  by protein in an alkaline medium with the highly sensitive and selective colorimetric detection of  $Cu^{+1}$  using a reagent containing bicinchrominic acid. The purple-colored reaction product of this assay is formed by the chelation of two molecules of BCA by one cuprous ion. The complex exhibits a strong

absorbance at 562 nm that is nearly linear over a broad working range (20 - 2,000  $\mu$ g/ml). The macromolecular structure of the protein, the number of peptide bonds and the amino acids cysteine, cystine, tryptophan and tyrosine are responsible for the color formation with BCA. Protein concentrations are determined and reported with reference to standards of a common protein such as BSA.

In this work, a dilution series of known concentrations of BSA was prepared and assayed alongside the unknown samples before the concentration of each unknown was determined based on the standard curve. It was very important that the buffer used for the dilution series of the standards was identical with the buffer of the samples to be assayed. 25  $\mu$ l of each standard or of unknown sample replicate was pipetted in a microplate well. 200  $\mu$ l of working reagent (50 volumes of reagent A: 1% BCA-Na<sub>2</sub>, 2 % Na<sub>2</sub>CO<sub>3</sub>·H<sub>2</sub>O, 0.16% Na<sub>2</sub>-tartrat, 0.4% NaOH, 0.95% NaHCO<sub>3</sub>, pH 11.25, mixed with 1 volume of reagent B: 4% CuSO<sub>4</sub>·5H<sub>2</sub>O) was added in each well. The plate was mixed thoroughly on a plate shaker for 30 sec before being incubated for 30 min at 37 °C. The plate was allowed to cool down to room temperature after which the absorbance at 562 nm was measured on a plate reader.

# **3.2.3 Protein Deglycosylation**

There are two methods for protein deglycosylation: the chemical and the enzymatic procedure. Hydrazinolysis of glycoproteins (82), although capable of removing both N- and O-linked sugars, results in the complete hydrolysis of the protein and the modification of many amino acids. A milder chemical method, such as the trifluoromethanesulphonic acid method (TFMS) (83, 84), leads to incomplete sugar removal, partial protein hydrolysis and modifications of several amino acids. On the other hand, the enzymatic deglycosylation provides complete removal of the N-linked sugars from the protein with no measurable side-reaction. In this study, protein deglycosylation was performed enzymatically under denaturing conditions (heating with SDS and  $\beta$ ME) to increase the yield of deglycosylation. The removal of the Nlinked oligosaccharides was performed using N-Glycanase (PNGase F, Prozyme). The only amino acid modification that occurs in this reaction is the deamidation of the arsparagine residue to aspartic acid after the removal of the sugar from this residue. There is no enzyme comparable to N-Glycanase to remove intact O-linker sugars. Monosaccharides must be removed by a serie of exoglycosidases until only the Gal $\beta$  (1-3)GalNAc core remains attached to the serine or threonine residue. O-Glycanase can then remove the core structure intact with no modification of the serine or threonine residues. Sialic acids attached to O-linked sugars can be removed by Sialidase A.

Samples were deglycosylated under denaturing conditions according to the protocol provided by the kit's manufacturer (Prozyme). 10  $\mu$ l of 5x incubation buffer (0.25 M sodium phosphate, pH 7.0) and 2.5  $\mu$ l of denaturation solution (2 % SDS, 1M  $\beta$ ME) were added to a maximum of 100  $\mu$ g of sample (dissolved in 30  $\mu$ l). The sample was heated for 5 min at 100 °C and, once cooled down to room temperature, 2.5  $\mu$ l of detergent solution (15% NP-40) were added. Finally, 1  $\mu$ l (approximately 5 mU) of each deglycosylation enzyme (N-Glycanase, Sialidase A, and O-Glycanase) was added to the solution and the sample was incubated for 3 h at 37 °C. The protein deglycosylation process was monitored by 1D SDS PAGE.

# **3.2.4 1D SDS-PAGE electrophoresis**

Sodium dodecylsulphate polyacrylamide gel electrophoresis (SDS-PAGE) is a method to resolve proteins according to their molecular size. The negatively-charged SDS molecules in the sample buffer bind to the heat-denatured proteins in a constant ratio (approx. 1.4 g SDS per g protein). As a result, SDS-loaded proteins migrate towards the positive pole in an electrical gradient, impeded by the polymerized and cross-linked polyacrylamide, at a mobility that is roughly proportional to their size.

The following protocols were used for Novex Bis-Tris precast SDS gels (Invitrogen).

# 3.2.4.1 Sample preparation and electrophoresis

Each sample was reduced and alkylated before being applied onto the SDS gel. Samples (approximately 15-20  $\mu$ g total protein) were mixed with the appropriate amount of 4x NuPAGE LDS sample buffer (1x NuPAGE LDS buffer contains 141mM Tris, 2 % LDS, 10 % Glycerol, 0.51 mM EDTA 0.22 mM Coomasie Blue G250 and 0.175 mM Phenol Red pH: 8.5 from Invitrogen). 100 mM freshly prepared DTT (in water) was added and the samples were incubated for 15 min at 70 °C. The samples were then allowed to cool down to room temperature and 300 mM Iodacetimide (aliquots of 1 M iodoacetamide in 300 mM Tris pH 8.8, 2.5% SDS, 10% Glycerol) was added. Each sample was incubated for 25 min at 45 °C before being loaded onto a 10 % acrylamide Novex Bis-Tris SDS gel (Invitrogen) that had already been placed in the Mini cell module (Invitrogen). 10  $\mu$ l of the prestained SDS molecular mass marker (See blue plus 2 from Invitrogen) was loaded in one well of the gel to calibrate the molecular mass of the separated proteins in each sample. The gel was run using the MOPS SDS running buffer system (20x MOPS SDS running buffer contains 1 M MOPS, 1 M Tris, 69.3 mM SDS and 20.5 mM EDTA, pH: 7.7 from Invitrogen) at 200 volts constant for approximately 1 hour typically until the front dye had reached the bottom of the gel.

### **3.2.4.2** Protein staining

Protein staining using colloidal Coomassie is based on the work of Neuhoff et al., (85). The method is based on the colloidal properties of Coomassie Blue dyes in aqueous or methanolic solutions in presence of inorganic acids and high salt conditions. The free dye in solution is greatly reduced due to the hydrophobic effect, resulting in low background and high affinity binding of the dye to the proteins fixed in the gel. A typical limit of detection of < 10 ng of BSA protein loaded onto a 1 mm 4-12 % acrylamide Tris Glycine gel can be obtained using this protein staining method.

After completion of the run, the gel was removed from the mini cell. The gel was first incubated in freshly prepared fixing solution (50% methanol, 10% acetic acid in deionized water) for 10 min to obtain a more efficient staining. The gel was then shaken for a maximum of 12 hours in the staining solution (20% Methanol, 20% Stainer A (containing ammonium sulfate and phosphoric acid) and 5% Stainer B (containing Coomassie G250) in deionized water), after which the gel was then destained in deionized water until a clear background was obtained.

# **3.2.5 Western Blotting**

A Western blot (alternately, immunoblot) refers to a method to immunodetect a specific protein, usually in a complex mixture, on a membrane support after electrophoretic separation. This process is performed in three steps. First, gel electrophoresis is used to separate native or denatured proteins by the length of the polypeptide (denaturing conditions) or by the 3-D structure of the protein (native/ non-denaturing conditions). Proteins are then transferred from the gel to a membrane support (i.e., nitrocellulose or PVDF) via electrotransfer. Finally the blot is processed for the detection of specific proteins using antibodies, the product of which is the final Western immunoblot.

In this protocol, protein transfer from SDS gel to PVDF membrane was achieved using the Wet blotting technique. A PVDF membrane (cut to the size of the gel) was activated (immersed) in methanol for 30 seconds, briefly rinsed with water, and then equilibrated in the Transfer buffer (NuPAGE Transfer buffer 1x: 25 mM Bicine, 25 mM Bis-Tris and 1 mM EDTA, pH: 7.2 complemented with 20 % methanol and 0.005% SDS) along with the two filter papers. Samples of interest were loaded and separated onto a 10% SDS Bis-Tris gel (Invitrogen) as described in the previous chapter. The gel was soaked in deionised water immediately after electrophoresis (for approximately 10 min) before to rinse it shortly in Transfer buffer before use. The XCell II SureLock Mini-Cell module (Invitrogen) was used

for the transfer of the proteins from the gel to the PVDF membrane. The sandwich of the PVDF membrane and the gel was placed in the XCell module according to the manufacturer's instructions. The transfer took place at 38 volts constant for 90 minutes with a starting current of 100 mA with the module kept cold in an ice bath.

After transfer, the PVDF membrane was rinsed briefly with deionised water and was stained with 0.1% Ponceau S for evaluating the efficiency of the protein transfer. The membrane was then destained with deionised water and was washed several times with TTBS buffer (50 mM Tris pH 8.0, 80 mM NaCl, 2 mM CaCl<sub>2</sub>, 0.1% Tween 20) until the stain was completely removed. Blocking was achieved by incubating the membrane in Superblock TBS blocking buffer (Pierce) and then in Blocking buffer (TTBS buffer plus 5% non-fat dried milk) for 30 min each. The membrane was then incubated overnight at 4 °C in blocking buffer with the primary antibody at an appropriate dilution. On the following day, the PVDF membrane was washed three times with TTBS buffer for 10 min each and 1 h in the blocking buffer. The membrane was then incubated for 90 min with the secondary antibody (HRP-conjugated) in the blocking buffer at room temperature. The membrane was washed subsequently three times with TTBS buffer for 10 minutes each. Immunodetection by chemiluminescence was performed by incubating the PVDF membrane in the ECL detection reagent (GE healthcare) for 1 min. Excess reagent was drained out and the membrane was wrapped up in a saran wrap. The blots were placed protein side-up in an X-ray film cassette and a sheet of chemiluminescence film (Hyperfilm ECL from Amersham Biosciences) was placed on the top of the membrane. The cassette was closed and the film was exposed for a given amount of time (typically, from 30 sec to 10 min) before being developed. This last step was repeated several times until an exposure time was considered as optimal from the signal point-of-view.

# 3.2.6 In-gel protein digestion

This protocol describes a method for the direct digestion of proteins in Coomassie- or colloidal blue-stained polyacrylamide gels. The absence of detergents and a minimal use of salt allow the direct analysis of the resulting digest by nanoLC-tandem mass spectrometry without an additional desalting step. In this study the protein digestion was performed by Trypsin, an enzyme that cleaves specifically after Lysine and Arginine except if the following amino acid is Proline.

The colloidal blue-stained gel was placed on a clean glass plate and the gel bands of interest were excised out of the gel using a clean scalpel. Each band was cut into the smallest pieces possible that were placed in an Eppendorf tube. The bands were destained first with 50%

ACN for 10 min and second with destaining solution (100 mM ABC, 30% ACN) for 10 min. The last step was repeated if necessary until the acrylamide pieces were completely colorless. The protein reduction/alkylation step was skipped as the sample was already reduced and alkylated prior to SDS PAGE. The bands were then dehydrated with 100% ACN for 15 min after which the bands were dried in a Speed Vac for 10 min without heating. The dried gel pieces were re-swelled in 50 µl tryptic digestion buffer (40 mM ABC containing 10 ng/µl Trypsin (Promega)) for 30 min. Additional buffer (5 mM ABC) was then added to the gel pieces if they were not completely covered with buffer. Digestion was carried out overnight at room temperature. On the following day, the supernatant was first collected and additional 5 mM ABC (50 µl) was added to the gel pieces for 15 min at 37 °C. After collection of the supernatant, the gel pieces were further extracted with 300 µl 100% ACN for 10 min at room temperature, after which the supernatant was again collected. The gel pieces were then extracted with 50 µl of 5% Acetic acid, 5% ACN at 37 °C for 15 min and the supernatant was collected. Finally, the gel pieces were extracted again with 300 µl 100% ACN at room temperature for 15 min. The above procedure has been adapted from several papers (86-88). The pooled supernatant was then dried in a speed Vac without heating and the peptide extract was kept at -80 °C until further use.

# **3.2.7 Mass spectrometry**

## **3.2.7.1 Packing of NanoLC columns**

An analytical fused silica emitter (75/360  $\mu$ m i.d./o.d., tip diameter 8±1  $\mu$ m, New Objectives) was packed with 12-15 cm of 3  $\mu$ m Reprosil C<sub>18</sub> A.Q. reverse phase material (Dr. Maisch). The resin was mixed with methanol (approximately 50 mg/ml) and the fused silica was packed at 170-200 bar using pressurized Nitrogen. The column was then rinsed with pure methanol at the same pressure and kept dried until use.

## 3.2.7.2 Method development for NanoLC ESI-MS/MS

Peptide samples were analyzed by nano liquid chromatography electrospray tandem mass spectrometry using an Ultimate 3000 nanoflow chromatographic system (Dionex) coupled to a LTQ-Orbitrap tandem mass spectrometer (Thermo Electron) equipped with a nanoelectrospray ion source (Proxeon Biosystems)

The peptide mixture of each sample was dissolved in 20  $\mu$ l of buffer A (2% ACN, 0.5% acetic acid). 10  $\mu$ l of the sample was transferred to a glass vial of 0.25 ml volume (sun – sri) of which 5  $\mu$ l were injected into the system at a flow rate of 450 nl/min at 100 % buffer A for 12

min. After loading, the flow was decreased to 250 nl/min and peptides were eluted from the reverse phase column as follows: 12—14 min, 0—5% buffer B (80% ACN, 0.5% acetic acid); 14—30 min, 5—30% buffer B using the curve 4 (slightly concave) of the Chromoleon software (Dionex); 30—90 min, 30—55% Buffer B using the curve 6 (slightly convex) of the Chromeleon software. The column was then washed for 15 min with 100 % buffer B at 350 nl/min, after which it was re-equilibrated for 25 min in 100% buffer A at 350 nl/min.

Peptides were analyzed by tandem mass spectrometry using standard operating parameters as follows: the electrospray voltage was set to 2.2 kV and the ion transfer capillary temperature was at 170  $\degree$ C. Survey scans (scanning range m/z 400-1500) were recorded in the Orbitrap mass analyzer at a resolution of 30,000 with the lock mass option (20) enabled. Data-dependent MS/MS spectra of the five most abundant ions from the survey scan were recorded in the LTQ ion trap using a normalized collision energy of 32% for MS/MS (30 ms activation, q=0.25) and a selection threshold of 500. Target ions selected for MS/MS were dynamically excluded for 30 sec.

#### **3.2.7.3 Data Processing Method and Protein Identification**

The raw data files of each LC-MS/MS run were processed using the SEQUEST search algorithm 27 (SEQUEST version 27.0, revision 12, Thermo Electron). Searches were performed against the in house-generated MouseGP database (Version January 2007, genome version mm8/NCBI36, 60862 entries). The MOUSEGP database is generated by taking the most recent version of all the non-redundant sets of Swissprot and Trembl sequences from human, mouse, rat, other vertebrates, drosophila, C. elegans and Yeast and blast the sequences against the mouse chromosomes. The putative exons are then assembled into genes. The alignments between genomic chromosome sequence and proteins are refined with GeneWise (89, 90), a tool that finds splice sites and corrects frame shifts. Data were searched with a mass tolerance of +/-5 ppm for parent ions and +/-1.0 Da for fragment ions. Methionines (reduced/oxidized; +15.9949 Da) were considered as differential modifications while cysteines were considered as fully carbamidomethylated (+57.0199 Da). Only fully tryptic peptides with no more than one miscleavage were considered for data analysis. Peptides were considered as unambiguously identified if their XCorr scores (91) exceeded 1.5, 2.0 or 2.5 for singly, doubly and triply charged ions, respectively, and if the corresponding  $\Delta$ Cn scores (the normalized Sequest XCorr score difference between the first and the second best peptide match,(91)) were larger than 0.2. In this study, only proteins for which at least two different peptides were identified were considered as successfully identified. The False

Positive Discovery Rate at the peptide level was estimated by searching the raw data files against a shifted database. This database, which is generated from MOUSEGP, has an identical number of proteins and tryptic peptides by keeping fixed the position of the arginines and lysines while the position of all remaining amino acids were left-shifted by two positions. The raw files were searched by using the above searching criteria and the raw spectra were submitted to the scrambled database for scoring. These spectra were binned based on their score and the number of spectra in each bin was counted and stored in the database. An objective estimate of the false positive discovery rate at the peptide level is obtained by comparing the distribution and the scrambled database (52, 92, 93). Using the criteria mentioned above, the false positive discovery rate for 1+, 2+ and 3+ charged peptides was estimated to be 7.4%, 3.2%, and 0.6%, respectively.

Comparison of the LC-MS raw data files based on the total ion current of the peptides was performed by using the Genedata RefinerMS (version 4.5) software suite. Software-specific settings were as follows: baseline subtraction (20% quantile value, m/z Window 10 Da, RT window 0.1 min); chromatogram retention time (RT) alignment (prior internal peak identification on m/z window with 5 points, RT window 0.5 min, gap penalty 0.75, RT search interval 100 scans); peak identification as in RT alignment; peak shaping (multiplicity: 67%); isotopic clustering (minimal charge 2, maximal charge 4, correlation threshold 0.5, maximal missing peaks 1, mass tolerance 0.05, ionization: protonation; mass consistency: peptides). The resulting peak table associates the m/z and RT of a feature with its extracted ion count (XIC) and signal-to-noise ratio (S/N) measured in each sample. Features with a median S/N<5.0 were excluded from the data analysis as these outliers displayed broad ranges of nonlinear chromatographic shifts across samples.

## 3.2.7.4 Sequence and topology analysis

The proteins' cellular location and topology were analyzed with a variety of tools as follows.

Prediction for signal peptide was performed using the in-house "signal\_anchor" software tool (<u>http://bioinfo.bas.roche.com:8080/sawicgi/sawi.cgi?signal\_anchor</u>) using an algorithm inspired by the web-based SignalPep tool (94) but using a support vector machine prediction model using Roche internal data rather than a neural net prediction model.

Membrane protein prediction was performed using either the "ALOM" software tool (<u>http://bioinfo.bas.roche.com:8080/sawicgi/sawi.cgi?alom</u>) as described by Klein P et al. (95),

or the web-based "TMHMM 2.0" (<u>http://www.cbs.dtu.dk/services/TMHMM-2.0/</u>), as described by Krogh A. et al. (96).

The version of the GO annotations (as described in Gene Ontology Consortium (2000)) used in this work was from June 2008. In this work, the multiple GO annotations of a protein were reduced to what was believed to be the most relevant entry according to the following rules:

- a) plasma membrane > ER, GOLGI, endosome > lysosme, microsome, peroxisome> mitochondria > cytoplasm, cytosol > nucleus > other
- b) integral > anchored > peripheral, associated to > no mention of membrane interaction
- c) any membrane interaction > proteasome, cytoskeleton, vesicle, etc. >extracellular

In doubt, the protein annotation of the SwissProt database was used to direct the selection to one or the other direction.

# 3.2.8 RNA extraction from the small Intestine

A typical mouse intestinal tissue (100 mg) contains about 150 µg total RNA. However, only 1.0–1.5% of it is accounted as mRNA. RNA molecules, compared to DNA, are relatively unstable. In order to ensure accurate gene expression analysis, it is important that the RNA analyzed truly represents the *in vivo* gene expression of the sample. This is complicated by the fact that changes can occur during handling of the sample and isolation of the RNA. Two major types of artifacts are known to occur. Gene down regulation and enzymatic degradation of RNA, due to ribonucleases (RNases), result in an artificial reduction of both nonspecific and specific mRNA species. At the same time, other genes can be induced during handling and processing of the sample. The combination of these two effects can result in a transcription profile that differs from the true *in vivo* gene expression pattern.

Efficient disruption and homogenization of the tissues under conditions that preserve the RNA stability is essential for the total RNA isolation procedure. In the current protocol, the freshly removed small intestine was flushed with PBS buffer (GIBCO) and RNA*later* (QIAGEN) to better preserve the RNA from degradation. Approximately 100 mg of tissue was then embedded in 1 ml TRI Reagent (Sigma). As reported by Chomczynski et al. (97) the phenol and guanidine thiocyanate contained in the TriReagent are effective inhibitors of RNases. The tissue was homogenized with Lysing Fast RNA Matrix D tubes (Bio 101 systems) using a FastPrep Cell disrupter (Thermo Savant) at a speed of 6 m/sec for 20 sec. The cell disruption process is due to the collision and energy of impact (both of which determine the effectiveness of the disruption process) are a function of the FastPrep® Instrument speed

settings and specific gravity of the bead material used. The homogenate was then separated into an aqueous and organic phase by adding 0.1 volume of chlorophorm. Alternatively the step of the homogenization of the tissue was replaced by grounding the tissue under liquid Nitrogen. In this case the TRI reagent was added to the grounded tissue and immediately after was following the step of the phase separation by addition of chlorophorm. In both cases the preparation were incubated on ice for 5 min and centrifuged at 12,000 x g for 15 min at 4  $^{\circ}$ C. The RNA was present in the aqueous phase, the DNA in the inter-phase, and the proteins in the organic phase. Next, the RNA was precipitated from the aqueous phase by adding 2 volumes of cold isopropanol. The preparation was incubated on ice for 15 min and centrifuged at 12,000 x g for 10 min at 4  $^{\circ}$ C. The precipitate was washed with 75% ethanol and centrifuged at 7,000 x g for 5 min at 4  $^{\circ}$ C. RNA aliquots were then stored at -80  $^{\circ}$ C until use.

# **3.2.9 RNA Electrophoresis**

The overall quality of an RNA preparation may be assessed by electrophoresis using a denaturing agarose gel; this type of analysis provides simultaneously some information about RNA yield. A denaturing gel system is suggested, because most RNAs form extensive secondary structure via intramolecular base pairing, preventing them from migrating strictly according to their size. The quality of the extracted RNA was assessed using 1% agarose denaturating gel. 1 g of agarose was added to 72 ml of triple distilled water and heated until it was dissolved. The mixture was cooled to 60  $^{\circ}$ C and 10 ml of 10x MOPS running buffer (10x MOPS buffer: 0.4 M MOPS, 0.1 M sodium acetate, 0.01 M EDTA, pH 7.0 adjusted with NaOH), 18 ml 37% formaldehyde (12.3 M) and 1 µl EtBr were added to the agarose solution. The gel was poured using a comb to form the wells for the samples. The gel was then assembled in a tank and 1x MOPS running buffer was added to cover the gel by a few millimeters.

Each RNA sample  $(1-3 \mu g)$  was mixed with 2 volumes of formaldehyde Load Dye (Ambion) and heated for 15 minutes at 70 °C. The gel was loaded and electrophoresis was performed at 5 V/cm until bromophenol blue (the faster migrating dye) had migrated as far as 2/3 of the length of the gel.

The gel was visualized on a UV transilluminator (EtBr fluoresces under UV light when intercalated into DNA or RNA). Intact total RNA will show sharp 28S and 18S rRNA bands (eukaryotic samples) on a denaturing gel. In an ideal case, the 28S rRNA band should be

approximately twice as intense as the 18S rRNA band, a good indication that the RNA is intact. Partially degraded RNA will have a smeared appearance, will lack the sharp rRNA bands, or will not exhibit a 2:1 ratio. Completely degraded RNA will appear as a very low molecular weight smear. For this effect, a RNA size marker was loaded on the gel to allow the size determination of any bands or smears and to serve also as a positive control to ensure the gel was run properly. Alternatively, RNA quality was assessed using the Experion Systen (BIO-RAD) an automated Electrophoresis station. The analysis of the samples was performed according to the manufacturer's instructions.

## **4. RESULTS AND DISCUSSION**

# **4.1** An improved protocol for the specific isolation of BBM from small intenstine

The first attempts to isolate BBM from the small intestine were performed following the protocol of Kessler et al. (79) developed initially for the kinetic measurements of sugar and mineral transporters in BBM. A piece of small intestine, or scrapped mucosa if a cleaner preparation was needed, was homogenized using a polytron and the cell debris was removed by a low-spin centrifugation step. The following step, a calcium chloride precipitation, was used to segregate the Brush Border Membrane (the apical side of the enterocyte's plasma membrane) from the Basolateral membrane (the lumen side of the enterocyte's plasma membrane). Due to the different polarity between the two sides of the membrane, the addition of CaCl<sub>2</sub> specifically precipitated the basolateral membrane, which could then be removed from the preparation by low-spin centrifugation, while the BBM membrane remained in solution (the exact mechanism by which the process is driven is not known). The enriched BBM fraction could then be collected by high-spin centrifugation and resuspended in an appropriate buffer for further analysis.

The degree of BBM enrichment from the small intestine was monitored by Western blot using a specific BBM marker (FATP-4) and a contaminant basolateral marker (Na+/K+ ATPase a1). The BBM fraction showed only a modest enrichment factor (approximately 10-fold compared to the crude lysate) and still contained a detectable contamination from the basolateral membrane (Fig. 4.4 and 4.5, see also below). Simultaneously, BBM preparations from three different mucosa intestinal sections were prepared to investigate the level of purification (at the protein level) obtained with the Kessler protocol. Survey of the literature indicated that the protein composition of the BBM changes along the intestine. Hence, a highly enriched preparation was expected to result in protein patterns that should differentiate each of the sections. Fig. 4.1 shows the 1D-SDS-PAGE analysis of the BBM preparations from proximal, central, and distal mucosa sections obtained from a pool of three mice. The obtained protein patterns were almost identical with each other, with no obvious difference allowing discrimination between the three sections, indicating that the BBM preparations contained a significant level of contaminants masking the BBM-specific proteins.

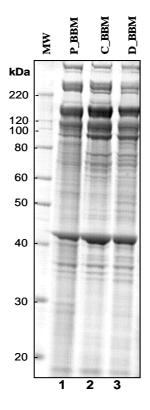

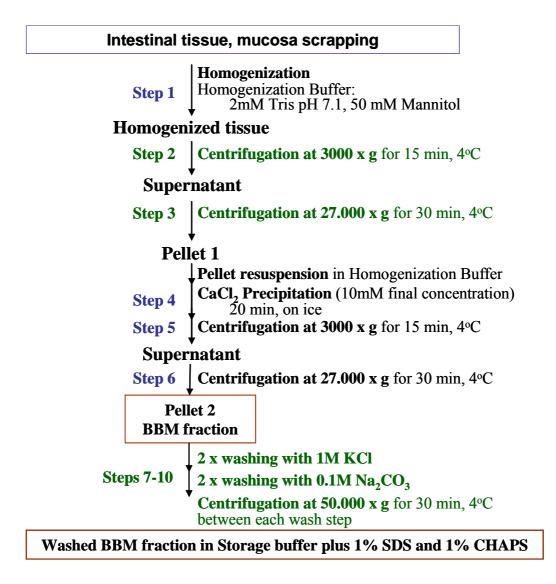

Figure 4.1: 10% 1D-NuPAGE Bis-Tris gel analysis of the Kessler BBM preparation from the three mucosa intestinal sections. 15  $\mu$ g total protein was loaded per sample. P\_BBM, C\_BBM, D\_BBM: proximal, central, and distal BBM preparation, respectively; MW: Molecular Weight marker.

For that reason a significant amount of time was spent to improve the performance of the original protocol. At first, my efforts were concentrated on the precipitation step, using several CaCl<sub>2</sub> concentrations to obtain more specific precipitation conditions, and on the centrifugation conditions in an attempt to increase the purity of the BBM preparation. Results of this optimization process were mitigated at best and did not yield any noticeable change in the quality of the preparation (data not shown). As a next step, I chose to focus my attention on improving the isolation protocol by adding purification steps which could remove a large part of the cytosolic and membrane-associated contaminant proteins so that a higher enrichment of the BBM's hydrophobic proteins could be achieved. First, a low- and high-spin centrifugation cycle was performed immediately after tissue homogenization so that the bulk of the cytosolic proteins could be removed from the membrane fraction before the CaCl<sub>2</sub> precipitation. Further, two washing steps using high salt (1 M KCl) and high pH (100 mM Na<sub>2</sub>CO<sub>3</sub>) were added after collection of the BBM fraction to remove most of the membrane associated proteins. A summary of the original and the modified protocol is represented on the flow diagram shown in Fig. 4.2.

**Figure 4.2:** *Flow diagram of a BBM preparation from mucosa or from intestinal tissue. The original steps from the Kessler protocol are marked in black. The steps 2, 3 and 7-10, which were added to the original protocol, are highlighted in green.* 

The improved BBM preparation protocol has been tested with intestinal tissue and mucosa scrapping, total tissue or in sections, with excellent results. The performance of the protocol and the level of BBM purification obtained from a total small intestine preparation are illustrated in Fig 4.3. Samples were collected along the BBM preparation and were analyzed by 1D-SDS-PAGE.

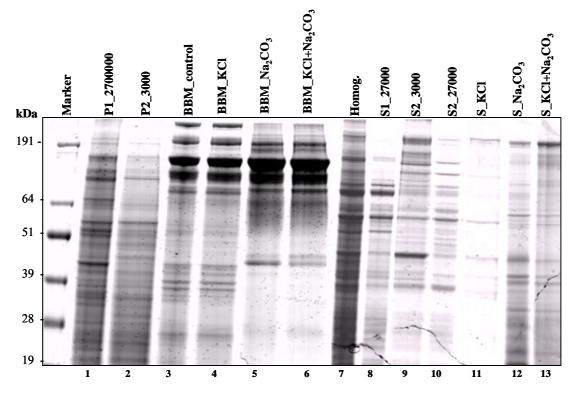

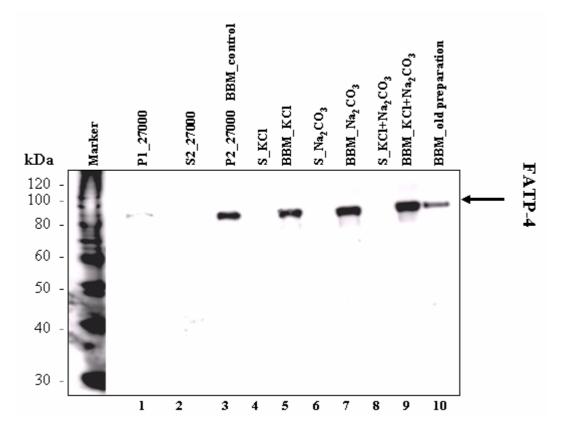

Figure 4.3: 1D-SDS-PAGE analysis of the fractions collected during the improved BBM isolation protocol. A sample amount of 15  $\mu$ g (according to the BCA protein assay) of total protein (except for the supernatants S1\_27000 and S\_KCl, where the maximum volume of sample was loaded) was loaded onto a 10 % 1D NuPAGE BisTris gel. Proteins were stained using colloidal Coomassie.

It was clearly demonstrated, as shown in the 1D-SDS-PAGE analysis of the collected fraction, that the initial low/high spin centrifugation step removed a considerable number of contaminant proteins prior to the CaCl<sub>2</sub> precipitation (Fig. 4.3, lane 8). Similarly, the high salt/high pH wash steps (1 M KCl followed by 100 mM Na<sub>2</sub>CO<sub>3</sub>, steps 7-10 of the protocol) of the initial BBM fraction also removed a number of membrane-associated proteins (Fig. 4.3, lanes 11, 12). Interestingly, the two washes clearly targeted different sets of proteins, as shown in the 1D-SDS-PAGE analysis.

The purity and the enrichment of the isolated BBM from total intestinal tissue was assessed by Western Blotting using FATP-4, a transmembrane, BBM-specific protein (Fig. 4.4), and  $Na^+/K^+$  ATPase a1, a transmembrane basolateral marker protein.

**Figure 4.4:** *FATP-4 Western Blot analysis of the fractions collected during the improved BBM isolation protocol.* 10 µg total protein were loaded for each sample. 1<sup>st</sup> antibody 1:2000 goat polyclonal specific for FATP-4 (Cat. No: sc-5835 Santa Cruz Biotechnology), 2nd antibody 1:7500 Horseradis peroxidase goat anti rabbit IgG. Lane 9 corresponds to the BBM purified with the new improved BBM isolation protocol while lane 10 corresponds to the BBM purified according to the Kessler's protocol.

The FATP-4 Western Blot analysis demonstrated convincingly that this BBM-specific protein was markedly more enriched in the BBM fraction collected with the improved protocol (approximately 30- to 50-fold compared to the crude lysate) than following the original Kessler's protocol. Comparison of the BBM fraction before the washes (lane 3) and the Kessler's BBM fraction (lane 10) illustrated that the first low/high spin centrifugation cycle was the key for improving the enrichment of the BBM fraction, most likely by removing the bulk of contaminant cytosolic proteins before the CaCl<sub>2</sub> precipitation step. The high salt/high pH wash steps also contributed to the enrichment of the FATP-4 BBM marker, although to a lesser extent, by the removal of additional cytosolic and membrane-associated proteins.

The quality of the improved BBM isolation protocol was also investigated with respect to the most likely BBM contaminant, the Basolateral membrane, using a Western Blot analysis against  $Na^+/K^+$  ATPase a1, a specific marker of this compartment (Fig. 4.5).

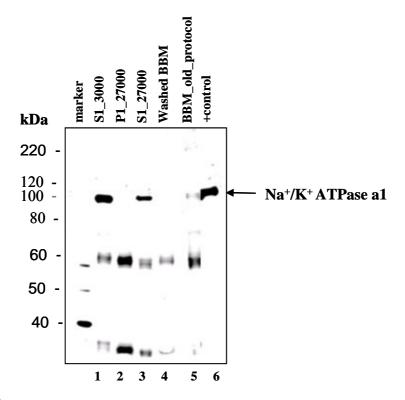

Figure 4.5:  $Na^+/K^+$  ATPase al Western Blot analysis of the fractions collected during the improved BBM isolation protocol. 10 µg total protein were loaded in each sample. 1<sup>st</sup> antibody 1:10000 mouse monoclonal specific for  $Na^+/K^+$  ATPase al (Cat. No: 05-369, Upstate), 2nd antibody 1:7500 Horseradis peroxidase rabbit anti mouse IgG. Lane 4 corresponds to the BBM purified with the new improved BBM isolation protocol while lane 5 corresponds to the BBM purified according to the Kessler's protocol. Lane 6, positive control (rat liver extract)

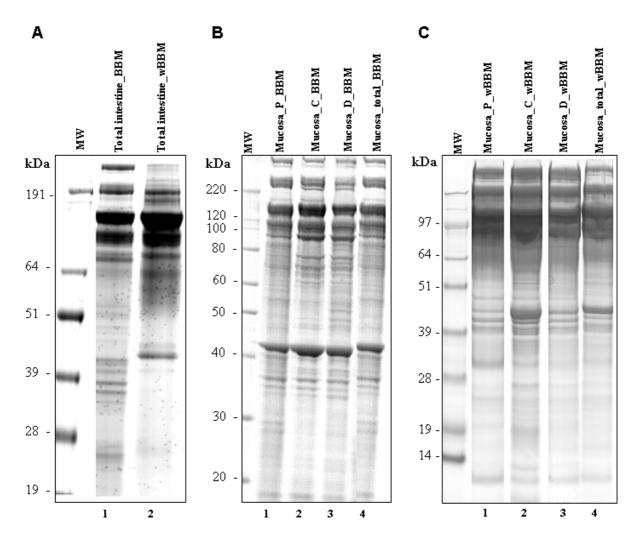

The Na<sup>+</sup>/K<sup>+</sup> ATPase al western blot analysis of the BBM fractions confirmed the excellent quality of the improved BBM preparation protocol. The 100 kDa band was assigned to Na<sup>+</sup>/K<sup>+</sup> ATPase al (according to the rat liver positive control) while the 60 kDa and 35 kDa signals most probably corresponded to antibody heavy and light chains (the secondary antibody was anti-mouse). There was no detectable basolateral membrane contamination (no signal for Na<sup>+</sup>/K<sup>+</sup> ATPase al in lane 4) in the BBM fraction prepared according to the improved isolation protocol while the BBM fraction prepared according to Kessler's protocol showed a low level basolateral membrane contamination (weak signal of Na<sup>+</sup>/K<sup>+</sup> ATPase a in lane 5).

In summary, an extended version of the original  $CaCl_2$  precipitation protocol from Kessler was demonstrated to yield a highly enriched and purified BBM fraction according to the Western Blot analyses against FATP-4, a specific BBM protein marker, and against Na<sup>+</sup>/K<sup>+</sup> ATPase a1, a known basolateral protein marker. In particular, the improved isolation protocol removed many cytosolic and membrane-associated proteins, thus facilitating a better enrichment of the hydrophobic BBM proteins, and yielded a BBM fraction with undetectable level of basolateral membrane, the major contaminant of BBM in all previous isolation protocols.

## 4.1.1 1D-SDS-PAGE analysis of BBM fractions

Throughout this study, BBM have been isolated from mice total intestinal tissue, from sections of intestinal tissue, from total intestinal mucosa, and from sections of intestinal mucosa. A BBM preparation from intestinal mucosa, for example, has the advantage that the starting material is highly enriched in enterocytes (the source cell type for BBM). Hence, as contaminations from erythrocytes and from the intestinal epithelium are avoided, the purity of the BBM preparations automatically increases. Conversely, scrapping mucosa from the inside wall of the intestine is a laborious process that has to be performed immediately after sacrifice (see also following sections on protein degradation). In certain types of experiments, because of logistic reasons, only intestinal tissue might become available. In this section, I summarize some of the findings on BBM preparations from diverse source materials.

Fig. 4.6 shows a composite 1D-SDS-PAGE gel analysis of BBM preparations from total intestine, from total mucosa, and from mucosa sections that have been prepared following either the original Kessler protocol or the improved BBM isolation protocol (see previous section). The section A of the 1D-SDS-PAGE represents the BBM fractions isolated from the total small intestine. The protein pattern obtained from the BBM prepared using the improved protocol (section A, lane 2) shows clearly that a number of proteins have been removed compared to the BBM fraction prepared according to the Kessler's protocol (section A, lane 1). A significant increase in the number of proteins can be observed, especially in the lower mass range, when the BBM is prepared from mucosa tissue instead from the whole small intestine (see lanes 4 of sections B and C). However, the protein patterns of BBM prepared using mucosa sections following the improved isolation protocol (section C, lanes 2-4) show significant differences between the three different sections, in contrast to the almost identical protein patterns obtained from BBM isolated from mucosa sections that have been prepared according to Kessler's protocol (section B lanes 2-4).

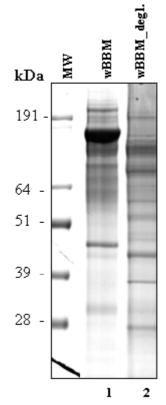

**Figure 4.6:** *ID SDS PAGE analysis of isolated BBM fractions. Section A: BBM fractions* from total small intestine prepared either according to Kessler's protocol (lane 1) or using the improved preparation protocol (lane 2). 15  $\mu$ g total protein were loaded per lane in a 10 % 1D NuPAGE Bis-Tris gel run in MOPS buffer system. **Section B:** *BBM fractions from mucosa tissue in sections (lane 1-3) and total (lane 4), prepared according to Kessler's protocol.* 15  $\mu$ g total protein were loaded per lane in a 10 % 1D NuPAGE Bis-Tris gel run in MOPS buffer system. Section C: BBM fraction from mucosa tissue in sections (lane 1-3) and total (lane 4), prepared according to the improved protocol. 30  $\mu$ g total proteins were loaded per lane in a 10 % 1D NuPAGE Bis-Tris gel run in MOPS buffer system. Section from mucosa tissue in sections (lane 1-3) and total (lane 4), prepared according to the improved protocol. 30  $\mu$ g total proteins were loaded per lane in a 10 % 1D NuPAGE Bis-Tris gel run in MES buffer.

In summary, the results of the 1D-SDS-PAGE analysis from BBM fractions prepared from different starting materials using two different protocols, in combination with the results obtained from the Western blots analysis (see section 4.1), were clearly indicative that the initial BBM characterization should be performed with mucosa as starting material following the improved isolation protocol to ensure maximum purity.

## **4.1.2 BBM preparation and protein degradation**

#### 4.1.2.1 Protein deglycosylation

A large number of proteins located in the BBM are highly glycosylated. Indeed, the 1D-SDS-PAGE analysis of a BBM fraction showed a large number of proteins tightly concentrated in the higher mass range of the gel. In order to better distribute those proteins in a wider mass range, and to achieve a better protein enzymatic digestion and peptide ionization in the mass spectrometer, an enzymatic deglycosylation process was performed under denaturing conditions (see section 3.2.3 for more experimental details). The BBM fraction was deglycosylated using N-Glycanase, Sialidase A, and O-Glycanase for 3 h at 37 °C. The outcome of the deglycosylation process was monitored by 1D SDS PAGE electrophoresis (Fig. 4.7)

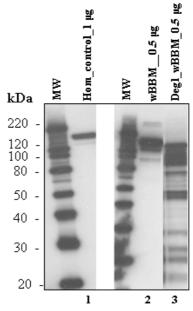

**Figure 4.7:** *1D-SDS-PAGE analysis of a BBM fraction before (lane 1) and after (lane 2) deglycosylation. 15 µg total protein were loaded per lane in a 10 % 1D NuPAGE Bis-Tris gel run in MOPS buffer. MW molecular weight marker* 

According to the 1D-SDS-PAGE analysis, the deglycosylation process was successful as the protein patterns of the native and deglycosylated BBM fractions were quite different from each other. In the deglycosylated sample, many protein bands have been shifted to lower molecular range and the proteins were distributed in a wider range of molecular masses.

#### 4.1.2.2 Western Blot analysis of Aminopeptidase N

The quality and the extent of deglycosylation of the BBM protein fraction was examined in more detail through the Western blot analysis of Aminopeptidase N, an abundant single transmembrane helix BBM protein marker predicted to bear 13 N-linked glycosylation sites. The Western blot analysis of Aminopeptidase N before and after the deglycosylation procedure should substantiate the completeness of the process and confirm that the molecular mass of Aminopeptidase N has been reduced to its predicted molecular mass (approx. 110 kDa). For this procedure, a polyclonal antibody raised against the full amino acid sequence (69-966 amino acids) of mouse Aminopeptidase N was used. The results of the western blot analysis are represented in Fig. 4.8:

**Figure 4.8:** Western blot analysis of Aminopeptidase N in a BBM fraction before and after deglycosylation. Lane 1: starting material (homogenized mucosa tissue); Lane 2: wBBM from total mucosa; Lane 3: deglycosylated BBM material from lane 2. Protein load is as indicated in the legend. 1<sup>st</sup> antibody 1:1000 goat polyclonal anti-Aminopeptidase N (Cat. No: AF2335, RnDSystems), 2nd antibody 1:7500 Horseradish peroxidase donkey anti goat IgG. MW, Molecular Weight marker

The results of the Western Blot analysis (Fig. 4.8) confirmed that Aminopeptidase N was an abundant BBM protein generating a very strong signal from a single band at around 170 kDa using 1 µg of total protein load (Fig. 4.8, lane 1). The generated signal was even stronger when the western blot was performed using 0.5 µg total protein load from the isolated BBM membrane (Fig. 4.8, lane 2). In contrast, the Western blot results obtained from the deglycosylated BBM fraction were quite different (Fig. 4.8, lane 3): the signal representative for Aminopeptidase N was shifted completely to a lower molecular mass, confirming that the protein deglycosylation procedure was successful. At the same time, however, a number of

additional signals at lower molecular masses than expected were also detected in the deglycosylated BBM fraction. As the primary antibody was polyclonal and was raised against the whole Aminopeptidase N protein sequence, we came to the conclusion that these additional bands could only represent Aminopeptidase N fragments, indicating that degradation was occurring during the deglycosylation process.

Protein degradation is, by nature, one of the primary roles of the small intestine. It was believed, however, that the use of the commonly available Ser- and Cys-protease inhibitors cocktail during the BBM preparation combined with the storage of the BBM in high concentration of detergents (1% SDS and 1% CHAPS) should be sufficient to inhibit proteolytic degradation. Additionally, it was very surprising that these peptidases should remain active during the deglycosylation process as the procedure was performed under reducing, denaturing conditions and the sample was heated at 90 degrees before the addition of the deglycosidases.

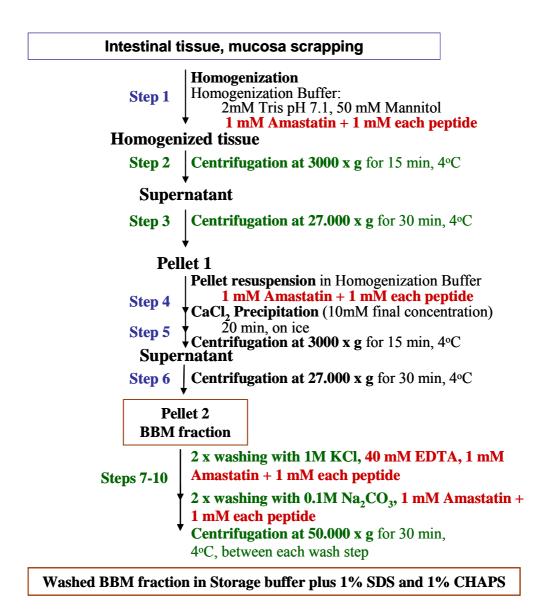

The presence of proteolytic enzymes in the BBM was confirmed by systematic protein identification of the glycosylated BBM fraction, as it will be discussed in the section 4.2, showing that the most abundant BBM proteins were indeed peptidases. These results, combined with the observation that abundant proteins were always identified in numerous fractions, confirmed that protein degradation plays a central role in the BBM.

### 4.1.2.3 Inhibition of protein degradation

The role of the many peptidases that were identified in the BBM membrane is to degrade proteins and long peptides to smaller molecules that can be easily transported through the small intestine. Based on the identification data, a high percentage of the most abundant BBM proteins was accounted by peptidases belonging to the family of His-Zn-dependent metalloproteases, such as Aminopeptidase N, Aminopeptidase A, Ileal dipeptidyl peptidase (NAALADase), Neprilysin, or Meprin, (see section 4.2 table 4.3), which are not inhibited by common Serin, Cystein proteinase inhibitors. Chemically, these peptidases can be inhibited efficiently using trifluoromethanesulphonic acid (83, 98). However, this procedure must take place in anhydrous conditions and this was clearly not compatible with the isolation protocol.

The importance to inhibit these peptidases should not be underestimated: among others, proteolytic activity can lead to false results in a western blot data interpretation (epitope degradation) or to major difficulties when a label free protein quantitation is used for the comparison of the samples (signal dilution in several fractions, irreproducible isolation procedure). In order to reduce proteolytic activity, two peptidase partial inhibitors that were

described in the literature to be active against His-Zn metalloproteases, Amastatin and Bestatin (80), were evaluated. Using the same Western Blotting analysis as described in the previous section, Bestatin did not appear to have any effect while Amastatin was found to lessen but not suppress the proteolytic activity in the BBM fraction (results not shown).

**Figure 4.9:** *Optimized flow diagram of a BBM preparation from mucosa or from intestinal tissue.* The original steps of the Kessler protocol are marked in black while the steps 2-3 and 7-10, labeled in green, were added to the protocol during this study (see Fig. 4.3). The steps where Amastatin, the peptide substrates, and EDTA were added to the protocol are labeled in red.

Superior results were obtained when Amastatin was used in combination with the addition of high concentration of peptide substrates, such as Angiotensin 1-5 and Met-Lys-Bradykinin, which could significantly compete out BBM proteins from degradation. Finally, according to the literature (99) divalent cations, such as  $Ca^{+2}$  and  $Mg^{+2}$ , activate His-Zn-dependent metalloproteases. It was then essential to remove the excess of  $Ca^{+2}$  after the  $CaCl_2$  precipitation and 40 mM EDTA was added to the first wash of the BBM membrane for this purpose. The flow diagram of the optimized BBM preparation, including the above modifications, is represented in the figure 4.9.

In order to check the level of inhibition, a Western blot analysis of two BBM fractions (no inhibitor; in presence of the inhibitor, peptide substrates and EDTA) was performed to compare the levels of degradation of Aminopeptidase N (fig. 4.10):

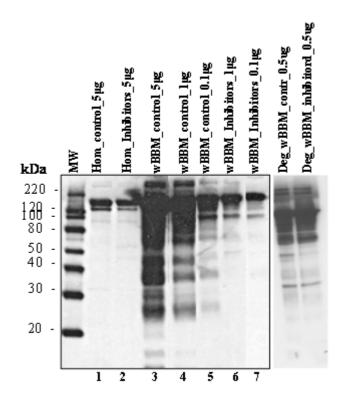

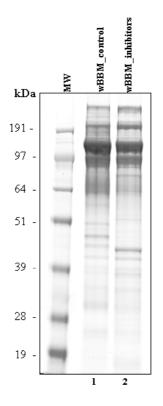

Fig. 4.10: Western Blot analysis of Aminopeptidase N of a control BBM (lanes 1, 2 following protocol as in Fig. 4.3), of a BBM fraction isolated with inhibitor, peptide substrates and EDTA lanes 3-7, following protocol as in Fig. 4.9), and of a deglycosylated BBM fraction (lane 8, 9, following protocol as in Fig. 4.8). Total protein load of BBM were loaded as indicated in the legend. Probing and detection conditions were as indicated in Fig. 4.8. MW, molecular weight marker.

The Western Blot analysis against Aminopeptidase N of a dilution serie of the two BBM fractions demonstrated that the combination of a partial inhibitor, Amastatin, of two peptide substrates in large amounts, and of EDTA to remove excess  $Ca^{2+}$  after  $CaCl_2$  precipitation, resulted in an approximately 10-fold reduction of degradation (Fig. 4.10, compare lanes 3-5

versus lanes 6, 7). Interestingly, the deglycosylation procedure appeared to completely void the relative protection conferred by the addition of the inhibitor, peptides substrates and EDTA. Once deglycosylated, the two BBM samples were observed with the same (extensive) level of Aminopetidase N degradation (Fig. 4.10, lanes 8, 9). Since protein degradation couldn't be controlled in any way during the deglycosylation process, the glycosylated form of the BBM fraction was chosen for further investigation in the current study.

The BBM fractions, isolated according to the modified protocol in presence and absence of inhibitors were compared in 1D SDS PAGE representation (Figure 4.11).

**Figure 4.11:** *1D SDS PAGE analysis of BBM fractions. Lane 1:* wBBM\_control, BBM isolated according to the modified protocol without addition of extra inhibitors (Fig. 4.3) *Lane 2:* wBBM\_inhibitor, BBM isolated according to the modified protocol in presence of Amastatin, the peptide substrates and EDTA. 15 µg total protein were loaded per lane in a 10 % 1D NuPAGE Bis Tris gel run in a MOPS running buffer system. MW, molecular weight.

The BBM fractions in presence and absence of the Zn-His metallopeptidase inhibitor, peptide substrates and EDTA, showed some differences in protein distribution on the 1D SDS PAGE analysis (figure 4.11). The BBM\_control lane (lane 1) showed, in comparison to the BBM\_inhibitors lane (lane 2), a higher diffusion of the proteins in the higher molecular masses and several prominent protein bands in the lower mass range, which is consistent with a higher degradation activity in the BBM fraction isolated without inhibitor. Characterization of the BBM fraction prepared in presence of Amastatin and the peptide substrates also

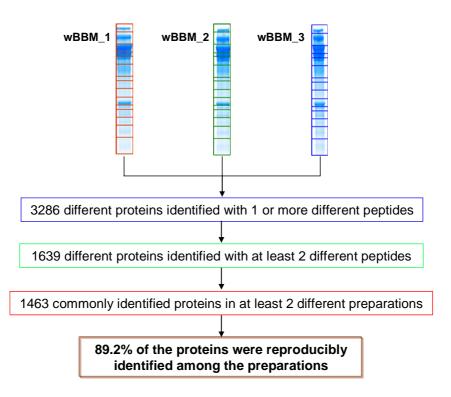

showed that protein identification was less redundant between SDS-PAGE bands (see also section 4.2) than with the BBM fraction isolated without inhibitor. Indirectly, this observation confirmed that protein degradation, the extent of which could be easily followed through the fragment distribution of abundant proteins in a SDS-PAGE analysis, was significantly reduced. As desirable as it would be, however, total inhibition of peptidase activity did not appear to be achievable without a major change of the BBM isolation protocol, which was outside of the scope of this study.

## 4.2 Protein identification of BBM mice intestinal mucosa

Proteins from the BBM mice intestinal mucosa were identified in triplicate using the following analytical strategy. A pool of intestinal mucosa (scrapped from 8 mice) was thawed, weighted, homogenized, and immediately divided in three equal parts. The BBM isolation procedure was performed in parallel for the three preparations. 30 µg of each purified BBM preparation were then analyzed on a single SDS-PAGE gel and each lane was then divided in 19 unequal bands to keep the protein amount in each band as similar as possible. The 57 resulting bands were then in-gel digested with trypsin and the extracted peptides were stored at -80 °C until further use. Each sample was then analyzed randomly (taking care not to analyze adjacent bands one after the other) by LC-ESI-MS/MS with one blank run between each sample to minimize carry over. The MS/MS analyses were then submitted to SEQUEST and the proteins identified in each of the 57 gel bands were stored in MSpresso to be then downloaded to Microsoft Excel.

A unique, non-redundant protein list for each BBM preparation was created as follows: for each band, redundant protein entries were first removed by collapsing a common group of proteins to one single entry, preferably with a SWISS-PROT entry, so to remove splice variants and multiple naming of the same protein from the list. Further, a protein list for each BBM preparation was created by combining the protein lists of the 19 bands, removing the redundant identification of a protein among the analyses but keeping the maximum number of different peptides found in a given band and the sum of peptide counts in the whole preparation. Finally, in the absence of a validated protein scoring to determine a false discovery rate, a protein was arbitrary considered to be unambiguously identified if two different peptides belonging to the same protein could be characterized in a given band. Similarly, a protein was considered to be constitutively part of the BBM preparation if it was identified unambiguously with at least two different peptides in one band in one given preparation and with at least one peptide in another BBM preparation. Fig. 4.12 provides a

short overview of the protein identification from the triplicate measurement of BBM preparation.

## Figure 4.12: Overview of the protein identification obtained from a triplicate BBM membrane preparation.

The 1307 proteins for which a valid SWISS-PROT/TrEMBL entry could be found are listed in appendix A1 (see also below). Proteins were ranked-ordered using their average peptide counts as a very rough estimate for their abundance in the sample. Spectral (peptide) counting is by far not an ideal measure for quantification purpose but this strategy is useful evaluating the dynamic range of the proteins included in the analysis. As the abundance of a protein rises in the sample, the amount of peptides derived from this protein also increases in the peptide mixture submitted to the mass spectrometer. Abundant peptides elute in wider chromatographic peaks than scarce peptides, and will therefore be picked up more often for MS/MS analysis. This strategy, however, tends to bias large, cytosolic proteins, which will generate numerous peptides, versus small proteins, for which only a small number of peptides can be found, or membrane proteins, of which only domains outside of the membrane regions are accessible for analysis by mass spectrometry (see also below).

The first 50 rank-ordered proteins of the triplicate preparation are listed in Table 4.1. As expected, a large number of those abundant proteins are part of the cytoskeleton, an essential component of the membrane structure. The quality of the preparation can be measured by the presence of a number of multiply-transmembrane proteins, such as the *Abcb1a* or the high-

affinity sodium/glucose cotransporter 1 transporters, that have been identified for the first time in a proteomics study. Similarly, the Niemann-Pick C1-like protein 1, a predominant protein of the BBM and a major player in cholesterol absorption, was also found among the 50 most abundant proteins of the preparation. Note also the presence of 9 proteases and 4 glycosidases in this list, mirroring the major function of the small intestine in degrading complex molecules to facilitate their ingestion.

Interestingly, the rank-order of the identified membrane proteins did not seem to be biased by the number of transmembrane domains that these proteins were predicted to contain. Thus, the Niemann Pick C1-like protein, a predominant protein of the BBM bearing 13 transmembrane helices, was identified with 32 different peptides and an average sum of 142 peptide counts. In contrast, the fatty acid transporter protein 4 (FATP-4), a protein bearing only two transmembrane helices, was identified with 3 different peptides and average sum of 3 peptide counts. In this preparation highly enriched for membrane proteins, the number of different peptides and the average sum of peptide counts reflected the relative abundance of a given membrane protein in the preparation. Thus, as an example, the FATP-4 protein could not be identified anymore in the preparation when the protein loading on the SDS-PAGE was reduced to 2/3 of the original amount (results not shown).

Table 4.1 The 50 most abundant proteins in the triplicate BBM preparation.Transmembrane proteins are noted in yellow, proteases are marked in pink.

Analysis of the nature and topology of the proteins identified in the triplicate BBM membrane preparation was performed as follows. Each of the 1463 protein sequences (which were originally derived from the mouseGP sequence database) was first matched to a SWISS-PROT/TrEMBL entry, resulting in 1307 valid entries (see appendix A1). Further, histone proteins, ribosomal proteins, as well as entries pointing to pseudogenes, were also removed from the pool of proteins to be analyzed to simplify the ensuing data analysis. (Table 4.2).

1463 mouseGP sequences	1206 SW/Tr sequence entries	further analyzed	
	38 histone protein entries	Not analyzed	
	54 ribosomal proteins	Not analyzed	
	9 pseudogenes	Not analyzed	
	156 unmatched gene products	Not found	

**Table 4.2:** Overview of the proteins identified in the triplicate BBM membrane preparation As there is no general method to comprehensively query the topology of a large number of protein species, the remaining 1206 entries were analyzed by partially overlapping strategies. First, proteins were categorized as "secreted", "membrane proteins" or "cytoplasmic" based on the predicted presence of a signal peptide targeting the protein for secretion (signal\_anchor tool) or on the presence of transmembrane sections anchoring a protein in a biological membrane (ALOM tool). The categorization "membrane protein" was further investigated with the TMHMM software package, which also allows predicting the number of transmembrane sections in a protein. Finally, the most relevant GO "cellular location" annotation of a protein was compiled to assess the nature and the topology of the 1206 investigated proteins (see appendix A1).

In a general manner, the three approaches provided similar results, albeit with considerable variation in respect to sensitivity and specificity. Fig. 4.13 shows the performance of the TMHMM and the ALOM algorithms (which both will flag a membrane protein) versus a manual search in the GO annotation filtered for the concept "integral membrane proteins".

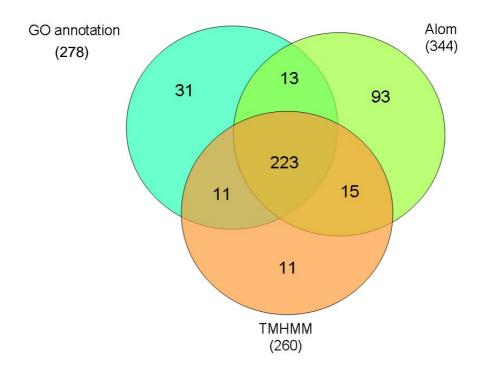

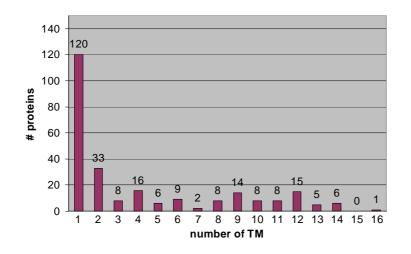

Figure 4.13: Predictive assignment of membrane proteins by the Alom software package and the TMHMM software package compared to the GO annotation of the 1206 proteins included in the analysis. The Go assignment included the terms "apical plasma membrane", "basolateral plasma membrane" and "integral to membrane".

The GO annotation method and the TMHMM algorithm roughly flagged the same proteins with more than 85% of the potential candidates commonly identified as a membrane protein. On the other hand, the Alom algorithm assigned about 20% more candidates as membrane proteins as the other strategies. This algorithm might be slightly more sensitive than TMHMM to pick membrane proteins, at the cost of a large increase in false assignment. However, compared to the GO annotation method, both algorithms appear to significantly underestimate the number of integral mitochondrial membrane protein (e.g. ATP synthase, H<sup>+</sup> transporting mitochondrial F1 complex, beta subunit, ATPA\_MOUSE, or solute carrier family 25 (mitochondrial carrier ornithine transporter), member 15, ORNT1\_MOUSE) and ion channels (e.g. voltage-dependent anion channel 2, VDAC2\_MOUSE). Most of those proteins most probably belong to the structural class of transmembrane  $\beta$ -barrel proteins, which can not be easily predicted even using the most recent software packages for structure predictions (100).

The transmembrane segment distribution of the 260 membrane proteins predicted by the TMHMM algorithm is shown in Fig. 4.14. The distribution of membrane proteins with one or two predicted transmembrane segments represented more than 50% of all the membrane proteins, closely following a whole genome predictive analysis of the number of protein with

transmembrane helices in human (101). The number of remaining membrane proteins was rather equally distributed among all the other membrane protein species with the interesting exception of the 7-transmembranes protein family (dominated by the GCPRs), which was underrepresented in this analysis while it is overrepresented and should account to 10% of all the proteins with transmembrane helices in human (Liu et al., 2001). This observation might reflect the main functional aspect of the enterocyte BBM, which is the transport of nutrients from the intestinal lumen to the lymphatic system rather than intracellular signaling.

#### **#proteins with TM segment**

Figure 4.14: Distribution of transmembrane segments in the 260 membrane proteins predicted by the TMHMM algorithm.

At first sight, the prediction of "only" about 260 membrane proteins out of a total of 1206 proteins (slightly more than 20%) might look disappointing. However, a detailed analysis of the GO annotation associated with the data showed a much more differentiated picture of the protein population that was characterized. As a note of caution, however, it should be noted that the vast majority of the protein analyzed was associated with more than one GO annotation, depending of the function and localization of the protein in a cell. Also, many of those annotations were rather vague or even sometimes contradictory. As a result, the GO annotations of all the considered proteins were manually filtered so to keep what was believed to be the most relevant entry in the context of the small intestine and the enterocyte function (see appendix B for a complete listing of the GO annotation kept in this analysis). Finally, the approximately 90 categories remaining after the first data compilation had to be further collapsed in organelle-based groups to enable a more general overview of the proteins (Table 4.3)

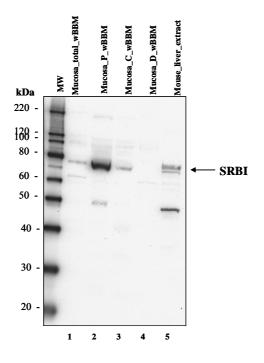

"Collapsed" GO annotation	# proteins	
associated to plasma membrane	52	
anchored to plasma membrane	60	
integral to plasma membrane	144	
associated to vesicle/ER/Golgi/endosome/microsome	80	
anchored to vesicle/ER/Golgi/endosome/microsome	29	
integral to vesicle/ER/Golgi/endosome/microsome	104	
ER/Golgi/endosome/microsome matrix	23	
associated to mitochondrial membrane	19	
anchored to mitochondrial membrane	2	
integral to mitochondrial membrane	16	
mitochondrial matrix	26	
cytoskeleton	98	
proteasome	29	
cytoplasm	331	
nucleus	31	
integral to nuclear membrane	1	
extracellular	35	
No or ambiguous "GO" annotation	126	

**Table 4.3:** Overview of the collapsed GO annotation categories retained for analysis. "associated": described an interaction with a membrane (such as e.g. "peripheral proteins"); "anchored": annotated as being anchored to the membrane through lipids or other types of membrane anchors; "integral": annotated as having at least one transmembrane segment.

As could have been expected from this type of membrane preparation, one of the most prominent groups of proteins in the BBM preparation comprised plasma membrane proteins, closely followed by a group of proteins interacting in large with the ER/Golgi/endosomal systems, which are known to be a major "contaminant" of a plasma membrane preparation. The vast majority of the proteins included in these two groups are channels, transporters, and membrane trafficking proteins most likely taking part in the import of nutrients in the enterocyte and the recycling of the membrane proteins back to the plasma membrane. A third important group in this preparation comprised cytoskletal proteins which have also been known to interact with the plasma membrane. In contrast, a comparatively small number of mitochondrial and nuclear proteins were characterized in this preparation, reflecting the high grade of purification achieved by this protocol. Only about a quarter of the proteins characterized in this preparation were annotated as "cytoplasmic", representing many metabolic pathways, but also proteins known to interact with membrane-bound proteins such as chaperonins or heat shock proteins. Finally, while the high number of ribosomal proteins might be reasoned by the tight interaction of the ER network with the plasma membrane, the presence of a large number of histone proteins in this preparation can not directly be explained, as they should locate exclusively in the nucleus.

## 4.3 Examples of protein localization

Some BBM proteins have been described in the literature to be localized in specific regions of the small intestine, so that the question was raised whether such specificity could be demonstrated using the BBM preparation described above. For this effect, BBMs from mice intestinal mucosa were prepared taking care to keep separate the proximal, central and distal segments of the small intestine. In this experiment, the three segments had equal length (the small intestine was cut in thee equal parts) although, according to the anatomical characteristics of the small intestine, the duodenum (the proximal part) is only a short section after the Pylorus, while the jejunum (the central part) accounts for 90% of the total length of the small intestine and the ileum (the distal part) is only a short terminus section. The BBM of each section were loaded in 1D SDS PAGE (see figure 4.6, panel C). Each gel lane was cut in 21 unequal gel bands and the samples were in-gel digested with trypsin. The extracted peptides of each band were then analyzed by LC-MS/MS and the raw data were processed according to the criteria previously described. The proteins identified for each section and for the total mucosa are listed in Appendix A2 along with their distribution along the sections (based on the maximum of different peptides and the total peptide counts for each protein). This experiment clearly demonstrates that some proteins were identified with more peptides from BBM isolated in section rather than from whole mucosa. In particular, there were several proteins that clearly located exclusively in only one of the three sections, such as the SR-BI receptor. The identification of this receptor was rejected in the BBM prepared from whole intestinal mucosa because it was identified with only one peptide. The protein identification carried out in each section separately confirmed the existence of the SR-BI receptor and its specific localization in the proximal part (see table 4.4 below). This finding was in agreement with a Western blot analysis against SR-BI, where the scavenger receptor was present almost exclusively in the duodenum segment (Fig. 4.15).

**Figure 4.15:** Western blot analysis of SR-BI in BBM prepared either from full intestinal mucosa or from sections. SR-BI immunoblot in BBM isolated from total mouse intestinal mucosa (lane 1) or from each section separately (lane 2-4). Mouse liver extract was used as a positive control (lane5). 30 µg of total protein was loaded in each case. 1<sup>st</sup> antibody 1:2500 rabbit polyclonal anti-SR-BI (Cat. No:NB 400-101, NOVUS Biologicals), 2nd antibody 1:7500 Horseradish peroxidase goat anti rabbit IgG.

In the sectional approach of protein identification in the BBM membrane, several proteins were found equally distributed along the small intestine (see examples on table 4.4). Some other proteins, such as FATP-4, were identified with more peptides in the BBM prepared from total mucosa than in sections. This might be due to more efficient washes (higher volume to mass ratio) of the BBM with high salt and high pH solutions. In this case, not only BBM contaminants were removed more effectively but also membrane-associated proteins and even integral proteins with one or two transmembrane helices were washed out.

GeneID	Data	Proximal	Central	Distal	Total	Protein Name	
237636	Max_Dif_pept	36	31	33	29	Niemann-Pick C1-like protein 1 precursor

39020	Sum_pept_count	205	356	218	297	rva(+)/ri(+) exchanger regulatory factor 5)	
26569	Max_Dif_pept	1		1	9	FATP-4	
20309	Sum_pept_count	1		2	10		

**Table 4.4:** *Examples of protein distribution along the BBM membranes of the small intestine. Comparison of BBM analysis in sections vs. total BBM.* 

According to the data presented on the table 4.4, it is most probable to assign the SR-BI receptor and the long-chain-fatty acid-CoA ligase to be exclusively located in the proximal part of the small intestine and the IBAT transporter to the distal part.

## 4.4 Cholesterol absorption

## 4.4.1 Identified proteins related to Cholesterol absorption

One of the stated goals of this study was to investigate whether a proteomics approach could confirm the presence of proteins known to be involved in cholesterol absorption in the BBM. Table 4.5 lists the proteins (among the 1300 proteins identified in the total BBM intestinal mucosa preparation) that have been described in the literature, mainly based on gene data or immunoassays, to play a role in cholesterol absorption in the enterocyte.

			Avg Pep	Max diff
Rank	Gene Symbol	Gene Description / Protein Header	count	peptides
6	Anpep	Alanyl (membrane) aminopeptidase	961	54
11	Abcb1a	Multidrug resistance protein 3 (MDR1A)	311	51
29	Npc1I1	Niemann-Pick C1-like protein 1 precursor	142	32
39	Anxa2	Annexin A2	115	29
65	Lgals4	Galectin-4 (Lactose-binding lectin 4)	80	11
66	Abcc2	Canalicular multispecific organic anion transporter 1	78	27

1056	Sec14L2	Sec14-like	3	3
1452	Scarb1	Scavenger receptor class B member 1 (SR-BI)	2	1

**Table 4.5:** *Potential protein candidates for intestinal cholesterol transport. The Rank order is a very rough approximation for protein abundance, based on the average peptide counts combined with the maximum different peptides for a given protein, not taking into account its size (large proteins generate more peptides than small ones) or its hydrophobicity (hydrophilic proteins generate more peptides than hydrophobic ones).* 

The Niemann-Pick C1-like 1 protein (NPC1L1) is a representative example of an abundant protein of the BBM preparation (table 4.5: rank order 29). This 13-transmembrane segments protein has been described to play a critical role in cholesterol absorption and it is believed to be the target of Ezetimibe, a cholesterol absorption inhibitor that blocks the transport of cholesterol and phytosterols across the BBM of enterocytes (13). Other studies have attempted to show that Aminopeptidase N (table 4.1: rank order 6) might represent the targeted protein of Ezetimibe (102). Further, malfunction or mutation affecting the two halfsize, 6-transmembrane segments ABC transporters ABCG5 and ABCG8 (table 4.5: rank order 192 and 102, respectively) can lead to a rare autosomal recessive disorder called sitosterolemia or phytosterolemia and is caused by hyperabsorption and impaired biliary secretion of cholesterol and plant sterols. The complex formed by Caveolin-1 and Annexin-2 (table 4.5: rank order 919 and 39) has been suggested as key element for the cholesterol trafficking from the BBM to the endoplasmic reticulum (103). Finally, a pioneering work of Hauser et al. (104) showed that cholesterol uptake is reduced if SR-BI, a 4-transmembrane segments receptor, is blocked by anti-SR-BI antibodies or by competitive ligands, such as

apolipoprotein A-I. Similarly, SR-BI overexpression was found to increase the intestinal cholesterol absorption (105). The role of many of the proteins mentioned above and of several other proteins, such as CD36, Galectin-4, and ABCB1, is the subject of hot debates. Several studies have supported their involvement in cholesterol absorption but their precise mechanisms of action have remained unclear so far (see for example a review from Levy E. et al. (106)).

It is worth mentioning here the presence of three lipoproteins, ApoA-I, ApoA-IV and ApoE, within the identified proteins of the BBM preparation. Their confident identification in this membrane preparation was rather unexpected as lipoproteins are by nature small, soluble proteins secreted by the liver and, therefore, they are not considered as constituents of the BBM. Lipoproteins were expected to be washed out from the BBM preparation during the several high salt (1M KCl) and high pH (100 mM Na<sub>2</sub>CO<sub>3</sub>) washes and to be identified in rather large amounts in these two fractions. Surprisingly, they were found in the BBM preparation, and not in the wash fractions (table 4.6).

Gene Name	wBBM	wNa2CO3	wKCI
ApoA-I	8	1	0
ApoA-I ApoA-IV	8	2	0
АроЕ	3	0	0

**Table 4.6:** *Maximum of different peptides obtained for the ApoA-I, ApoA-IV and ApoE proteins. Identification of the three apolipoproteins in the BBM fraction, the KCl and Na*<sub>2</sub>CO<sub>3</sub> wash fractions.

The finding that the three lipoproteins (ApoA-I, ApoA-IV and ApoE) were strongly enriched in the BBM fraction postulates a strong interaction between these lipoproteins and a BBM receptor or transporter. Indeed, two lipoproteins receptors, LRP-1 and Cubilin, were identified among the BBM-identified proteins; LRP-1 was shown to directly interact with ApoE (107) while Cubilin (by itself not a transmembrane receptor, but rather a co-transporter most probably located on the luminal side of the enterocyte plasma membrane) has been documented to interact with ApoA-I (108). Interestingly, in the kidney proximal tubule, cubilin interacts strongly with another receptor, megalin (also known as LRP-2) which is postulated to mediate internalization of cubilin and its ligands. Megalin, however, could not be identified in our study and was shown by mRNA study to be only present in the distal part of the intestine (109). Finally, as noted above, the SR-BI receptor has also been shown to interact with the apolipoprotein ApoA-I (110). In addition to the apical surface localization of the above described proteins (table 4.5), intestinal cholesterol transporters have also been detected in intracellular compartments. For example, SR-BI has been described to be mainly localized in the microvillar membrane of enterocytes in the fasting state, but was endocytosed during absorption of dietary fat (111). The role of NCP1L1 in cholesterol trafficking has also been documented: while it is mainly observed in endocytic recycling compartments as long as internal cholesterol pools are abundant, it is rapidly translocated to the plasma membrane in situation of cholesterol uptake (112).

These findings suggest that intestinal cholesterol transporters may also act intracellularly, mediating the movement of cholesterol from BBM to various organelles. In particular, they may assist in the shuttling of cholesterol from BBM to the endoplasmic reticulum where the incoming cholesterol represents the major source of substrate for ACAT and restrains HMG-CoA reductase activity (113). The localization of several transporters and other cholesterol absorption related proteins to several organelles shows that the process of cholesterol absorption is probably much more complicated than is known at this point of time. More studies will clearly be required to help understand the molecular mechanism of intestinal transporter-mediated cholesterol trafficking and regulation.

## **4.4.2** Comparison of protein expression in the BBM of wild type mice and ApoE knockout mice

One of the most widely used mouse models to study dislipidemia is the apolipoprotein E– deficient mice (ApoE-/- mice), in which targeted deletion of the *apoE* gene leads to severe hypercholesterolemia and spontaneous atherosclerosis. ApoE is synthesized in the liver and in macrophages and has a number of important anti-atherogenic functions. As a constituent of plasma lipoproteins, it serves as a ligand for the cell-surface lipoprotein receptors such as LDL-receptor (LDLr) and LDLr-related proteins (LRPs), thereby promoting the uptake of atherogenic particles from the circulation. Consequently, homozygous deletion of the apoE gene in mice results in a pronounced increase in the plasma levels of LDL and VLDL attributable to the failure of LDLr- and LRP mediated clearance of these lipoproteins (114).

The finding that ApoE strongly interacts with the BBM membrane (for details see § 4.4.1), added to the fact that many proteins involved in cholesterol absorption could also be identified using our protocol, encouraged us to investigate in more details the protein expression differences that could be observed in the BBM membrane of wild type mice versus ApoE knockout mice using the same proteomics approach as described above. Possible

differences in protein abundance could contribute to shed a better understanding in the mechanisms of high cholesterol absorption observed for the ApoE knockout mice.

The isolated BBM fractions of a pool of four male ApoE-deficient mice (B6.129P2-Apoetm1Unc/Crl) and four non-transgenic male mice of the same genetic background and age, were loaded in triplicate onto a 1D NuPAGE gel (see figure 4.16).

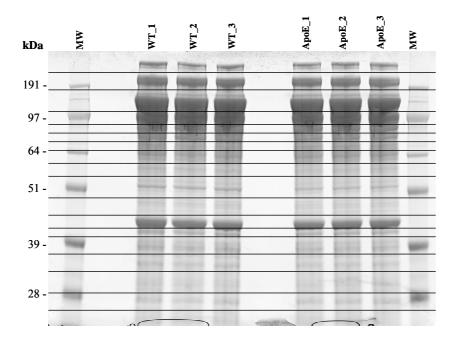

Figure 4.16: 1D SDS-PAGE gel representation of the BBM fractions of wild type and ApoE-KO mouse. Each fraction (30  $\mu$ g total proteins per lane) was loaded in a 10 % 1D NuPAGE Bis-Tris gel run in MES buffer.

The gel bands of the fractions were cut and in-gel digested with trypsin. The extracted peptides of each band were then analyzed by LC-MS/MS and the proteins of each band were identified according to the criteria that have been described at the § 3.2.7.2-3. Identical bands of the compared BBM fractions were analyzed sequentially with washing intervals, to achieve the best possible technical reproducibility.

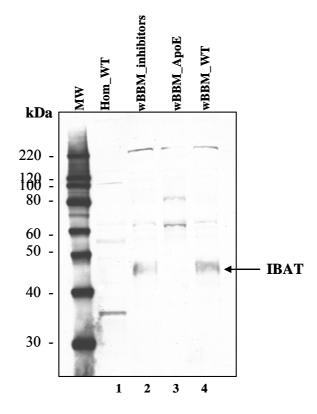

It was reinsuring that, in large, the identified BBM proteins in this experiment were identical to the BBM proteins that were identified in the previous study (see § 4.4.1). Most interestingly, several differences in protein abundance (based in peptide counts and number of different peptides) were clearly observed between wild type mice and ApoE KO mice. Since the study did not follow any formal quantification workflow, and only technical replicates were performed, we concentrated our interest only in proteins with major difference in abundance between the two types of mice, summarized in Table 4.7.

**Table 4.7:** *Examples of protein abundance differences between ApoE KO and wild type mice. Proteins labeled in yellow have been described to participate in cholesterol absorption while those showing a major change in abundance are highlighted in red.* 

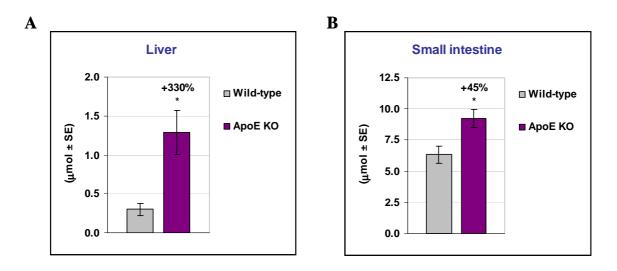

According to the data presented in Table 4.7, the Ileal Sodium/bile acid cotransporter (IBAT) and apolipoprotein A-I were confidently identified in the wild type mice but were completely absent in the ApoE knockout mice. This finding was confirmed in all the technical triplicates.

These findings were further validated using Western Blot analysis, and the result for IBAT is shown in Fig. 4.17. Unfortunately, the Western Blot analysis for Apo-AI was inconclusive (complete absence of signal).

**Figure 4.17:** Western blot analysis of IBAT. Lane 1, Homogenized intestinal mucosa tissue from WT mice with the same genetic background as the ApoE KO. Lane 2, BBM isolated from the total mouse intestinal mucosa of control mice C57B/6J. Lane 3, ApoE knockout mice and (lane 4) WT mice with the same genetic background as the ApoE-KO mice. 1<sup>st</sup> antibody 1:500 goat polyclonal anti-IBAT (Cat. No: sc-27493), 2nd antibody 1:7500 Horseradis peroxidase donkey anti goat IgG. MW, molecular weight marker.

Due to its function, IBAT's down-regulation was expected to have an impact on the bile acid metabolism in the ApoE-knockout mice. For this purpose, a separate in-house study investigated the bile acid pool size and composition in apoE-deficient mice compared to that in wild type mice. Results of this study showed that the liver and intestinal bile acid pool sizes were significantly increased in the apoE-deficient mice compare to the wild type mice (Evelyne Chaput, unpublished data; see Fig. 4.18). Thus, the increased bile acid production in the liver is consistent with disrupted bile acid re-uptake from the intestinal lumen, as expected from reduced IBAT protein expression, and increase the secretion of bile acids in the pancreatic fluids. The increased amount of bile acids in the intestinal lumen might explain why cholesterol absorption is higher in apoE KO mice, since the cholesterol molecule is better solubilized and more easily absorbed. This scenario is well supported by our data, but additional studies need to confirm these findings.

**Figure 4.18:** Graphic representation of the total bile acids in liver (panel A) and small *intestine* (panel B) in ApoE knockout mice and wild type mice. The total bile acids are a sum of all the individual bile acids determined by GC-MS (Adapted from Evelyne Chaput, unpublished data).

It is worth mentioning that conflicting data have been reported for the ApoE KO mice in the literature. For example, in disagreement with our observations, Hakansson et al. (115) reported that the bile acid pool size of apoE KO does not differ from that of wild-type mice. In addition, the authors report an increased IBAT activity based on the intestinal absorption of tauro-23-[75Se] selena-25-homocholic acid. In a contradictory report, and in agreement with our data, Woollett et al. (116) claim that plasma cholesterol and cholesterol absorption is higher in the ApoE KO mice than in the wild type. Interestingly, all these studies were based on gene data and on pharmacokinetic studies while our findings are based on protein-level datasets, which might be closer to the biological realm of the small intestine thann the above mentioned studies. Another interesting aspect is that most studies focus on the cholesterol absorption and the function of the intestine as a consequence of the cholesterol metabolism in the liver. Here, our data suggest that at least a part of the regulation of the cholesterol absorption happens in the small intestine independently of the liver metabolism. As a matter of fact, it could well be that the critical control elements of cholesterol metabolism are trigged at the small intestine level and that the liver is responding to this trigger rather than to lead it.

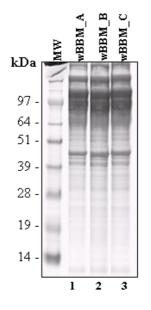

# 4.5 Assessing the reproducibility of the improved BBM preparation

In section 4.2, the measurement of a triplicate BBM preparation at the protein identification level (using rather stringent criteria) resulted in almost 9 proteins out of 10 being identified in at least two of the three replicates, a very encouraging result as to obtain BBM preparations in a reproducible and quantitative fashion. In the following paragraphs, we studied in a

systematic manner the technical steps that might affect most strongly the reproducibility and the stability of the BBM preparation, from the initial lysis step until the protein identification by LC-MS/MS. The inherently variable proteolytic activity of the numerous peptidases located in the BBM membrane was an additional reason to verify the reproducibility of the protein identification. Overall, the technical evaluation of a biological preparation represents an important first step to know how reproducibly identical samples can be prepared. It is also a necessary condition to evaluate with some probability to which extent the protein expression difference between sample and biological groups has to vary to become significant.

## **4.5.1 BBM preparation procedure**

The BBM material required for the reproducibility experiment was generated by performing three technical replicates of the BBM preparation starting from the same intestinal mucosa pool of eight mice used in the protein identification experiment described in section 4.2. As mentioned above, the optimized BBM preparation protocol included the addition of Amastatin and the peptide substrates to all steps to reduce the proteolytic degradation to a minimum (see Fig. 4.9). The three BBM preparation technical replicates were analyzed by 1D SDS PAGE to ensure that the protein distribution between the three replicates were identical (Fig. 4.20).

**Figure 4.20:** *ID SDS PAGE analysis of the three BBM replicates wBBM\_A, wBBM\_B and wBBM\_C (lane 1-3).* 30 µg of protein were loaded per lane in a 10 % 1D NuPAGE Bis Tris gel run in a MES running buffer system.

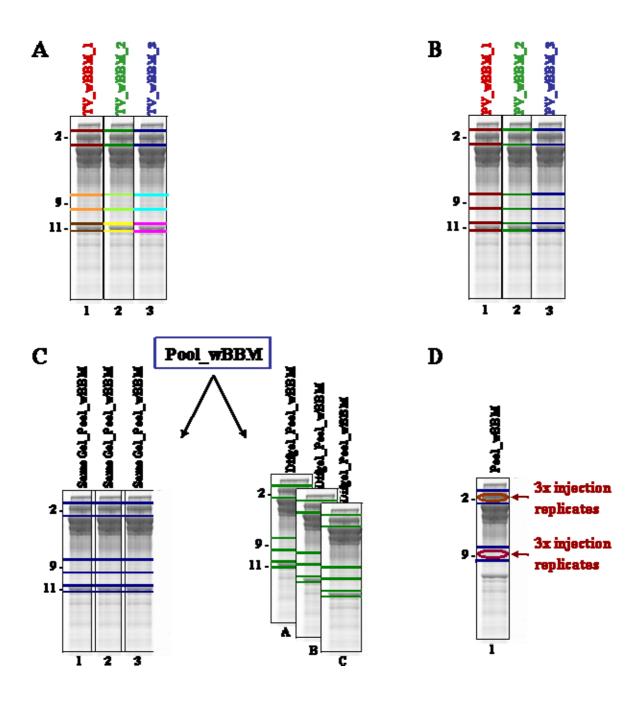

#### **4.5.2** Comparing the variability of the technical steps: design of experiment

A systematic approach to study the variation that each technical step added to the total variability is shown schematically in Fig. 4.21. The variability of the preparation was examined using these following parameters:

- a) Preparation variation (is the preparation reproducible?)
- b) SDS-PAGE variation and band excision (what happens if banding patterns are not absolutely reproducible?)
- c) LC-MS/MS variation (how reproducible is a LC-MS/MS analysis?)

All these experiments were evaluated on the basis of three representative SDS-PAGE bands, Band 2, Band 9, and Band 11. Band 2 represented a very abundant, very well defined high molecular mass band (expectation: excellent reproducibility) while Band 9 represented a diffuse, very faint band (expectation: not so good reproducibility). Band 11 also displayed a well defined band but differed from Band 2 by the fact that the proteins present in the mass range of the gel might also encompass proteolytic products (expectation: average reproducibility).

The analysis of the three technical replicates as displayed in Fig. 4.21, Panel A, with the gel bands excised serially and analyzed in a random order, using several batches of LC buffers and LC columns (as it was done for the identification experiment described in section 4.2), was representative of the effects observed if most of the sources of technical variations were taken into account in the study and provided therefore an estimate for the maximum technical variability that could be expected if biological or technical replicates could not be analyzed concomitantly. The analysis of the second set of three technical replicates of the BBM preparation loaded in the same gel (Fig. 4.21, Panel B), with the gel bands excised simultaneously (horizontally) and analyzed using the same batch of LC buffers or LC column provided the level of variability related mainly to the BBM preparation since all the following steps remained constant (negligible gel excision, column or buffer variability). The influence of the gel excision on the analysis reproducibility was investigated in more details using a pooled BBM preparation (generated by mixing an equal amount of total protein from each BBM preparation) loaded three times on one SDS-PAGE gel compared to the loading of the same pooled BBM preparation on three different gels (Fig. 4.21, panel C). Finally, replicate injections of the protein digests of band 2 and 9 were representative for the variability coming from the LC/MS system since LC column buffers remained the same for the whole analysis. The variability that was caused by the column or buffer change was estimated by the LC-MS analysis of a 50 fmol standard peptide mixture that was regularly analyzed between samples.

**Figure 4.21:** Schematic representation of the experimental design to estimate the variability of each technical step. Three representative bands were chosen for all analyses: 2, 9 and 11. All the samples of this experiment (except the ones from panel A) were measured using the same batch of LC column and LC buffers. **Panel A: Total variation (TV).** 1D SDS PAGE representation of the three technical replicates of the BBM membrane preparation. The samples were loaded in adjacent lanes but the bands were cut serially. This panel is identical to the samples that were analyzed for the BBM protein identification in section 4.2. **Panel B: Preparation variation (PV).** 1D SDS PAGE representation of the three technical replicates of the BBM membrane preparation. The samples were loaded in adjacent lanes and the bands were cut horizontally. **Panel C**: A pool of the three technical replicates of BBM was generated (equal amount of protein from each fraction). 30 µg total proteins from the pooled BBM were loaded three times in the same gel in adjacent lanes (lanes 1-3) and once in three different gels (lanes A-C). **Panel D:** The bands 2 and 9 of the pooled BBM (see also Panel C, lane 1) were injected three times into the LC-MS system. See text for more details.

## 4.5.3 Estimation of experimental reproducibility

The reproducibility of the technical steps and of the BBM preparation was estimated based on two different analyses. In the first approach, samples comparison was based on the identification rate in the samples considered. The number of commonly identified proteins in each representative band (2, 9 and 11) within the three replicates of each technical step was illustrated in the form of Venn diagrams. In the second approach, sample comparison was based on the total ion current of each sample's ion chromatogram. Datasets were processed with the Gene data software using the processing filters that have been described in the § 3.2.7.3.

## 4.5.3.1 Estimation of experimental reproducibility based on Protein identification

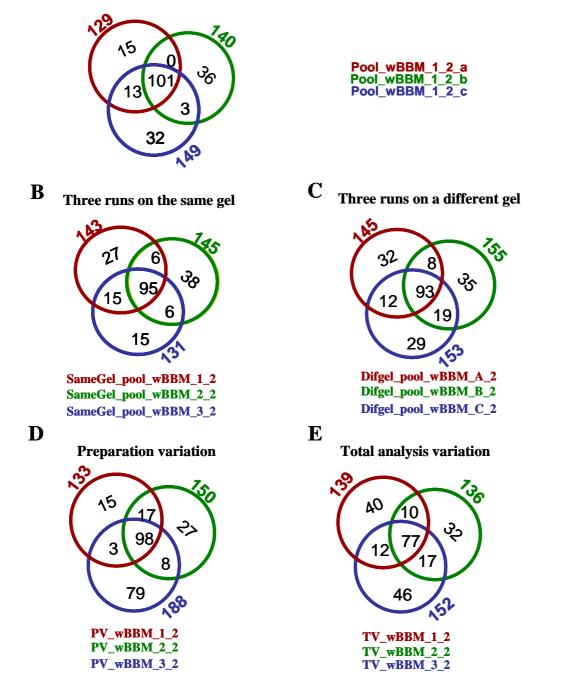

The study of the variability of each technical step based on protein identifications was performed using a set of rules that was different from the identification study. In particular, for the purpose of this investigation, proteins with one identified peptide were also considered as successfully identified. Sample comparison was performed in the form of Venn diagrams as there was no simple method to measure similarity between three samples.

### 4.5.3.1.1 Venn diagrams representation

Venn diagrams are a schematic representation to represent all the possible mathematical or logical relationship between groups. Each group is usually represented in the form of a circle, and overlapping area (intersections) stands for the similarity between groups. In this study, triplicate measurements of the three bands 2, 9 or 11, were compared to each other along the different technical steps. The Venn diagrams of all identified proteins in band 2 categorized by technical step are shown in Fig. 4.22. Each Venn circle represents an LC-MS analysis and the number of identified proteins for the band 2 in every of those analysis. The number outside the circle indicates the total number of proteins that have been identified with at least one peptide in this sample. The intersection between two circles shows the commonly identified proteins between the two compared samples, while the intersection of the three triplicates shows the number of commonly identified proteins in all the three compared samples. The triplicate injections of the band 2 from a BBM pool preparation (fig. 4.22, Panel A) was expected to exhibit the least variability of all the technical steps considered because it reflects the variability of the measurements in the mass spectrometer alone, keeping all other technical steps (nano LC column and buffers) constant. Comparison of the results shown in Panels B and C provides a measure about the variability that is due to the manner SDS-gel

Α

**Injection Replicate** 

**Figure 4.22:** Venn diagram representation of a triplicate analysis of the band 2 considering the variability of different technical steps. Panel A: Comparison of a triplicate injection of Band 2 obtained from a BBM pool preparation. Panel B: Triplicate comparison of Band 2 obtained from a BBM pool preparation loaded in adjacent lanes of the same gel. Panel C: Triplicate comparison of Band 2 obtained from a BBM pool preparation loaded in three different gels. Panel D: Triplicate comparison of Band 2 obtained from the three BBM preparation. All LC-MS technical steps were kept constant. Panel E: Triplicate comparison of Band 2 obtained from the three BBM preparations taking into account all technical variability (e.g. including LC-MS) into account.

bands were excised, while panel D's Venn diagram is showing the variability between the three BBM preparations since the samples were injected sequentially into the LC-MS system and all LC-MS technical steps were kept constant. The Venn diagram in Panel E reflects the variability observed for the proteins identified in Band 2 for the three BBM preparations when the samples were analyzed in a random fashion that is, taking into account all the technical variability of all the steps. Figure 4.23 and 4.24 show the Venn diagrams for the corresponding analysis of band 9 and 11.

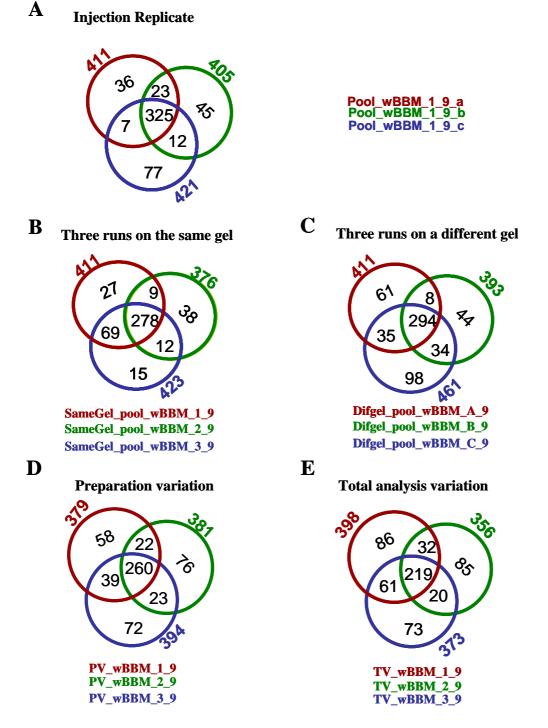

Figure 4.23: Venn diagram representation of a triplicate analysis of the band 9 considering the variability of different technical steps. Panel A: Comparison of a triplicate injection of Band 9 obtained from a BBM pool preparation. Panel B: Triplicate comparison of Band 9 obtained from a BBM pool preparation loaded in adjacent lanes of the same gel. Panel C: Triplicate comparison of Band 9 obtained from a BBM pool preparation loaded in three different gels. Panel D: Triplicate comparison of Band 9 obtained from the three BBM preparation. All LC-MS technical steps were kept constant. Panel E: Triplicate comparison of Band 9 obtained from the three BBM preparations taking into account all technical variability (e.g. including LC-MS) into account.

## **Estimation of variation for the band 11**

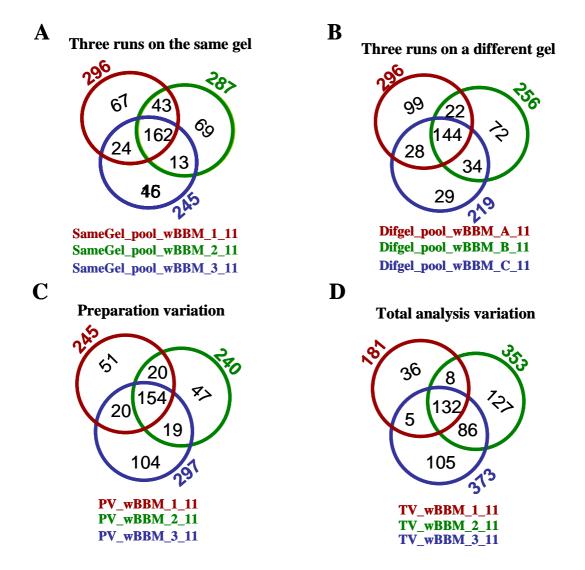

Figure 4.24: Venn diagram representation of a triplicate analysis of the band 11 considering the variability of different technical steps. Panel A: Triplicate comparison of Band 11 obtained from a BBM pool preparation loaded in adjacent lanes of the same gel. **Panel B:** Triplicate comparison of Band 11 obtained from a BBM pool preparation loaded in three different gels. **Panel C:** Triplicate comparison of Band 11 obtained from the three BBM preparation. All LC-MS technical steps were kept constant. **Panel D:** Triplicate comparison of Band 11 obtained from the three BBM preparations taking into account all technical variability (e.g. including LC-MS) into account.

The number of commonly identified proteins in bands 2, 9 or 11 across the different technical steps provides a first overview about the variability of each technical step. A graphic representation of the commonly identified proteins in two or three replicates, for each band and for each technical step is shown in Fig. 4.25.

Based on these results, it is apparent (and reinsuring) that the injection replicates show the highest reproducibility in respect to the number of commonly identified proteins, that is, the set-up and the operation of the LC-MS system was appropriate and reproducible for the number of proteins and the dynamic range expected for a 1D-SDS-PAGE band. Interestingly, the manner by which gel bands were cut (horizontally or one lane after the other) added some variability but the overall effect at the identification level was surprisingly moderate, indicating that, if proper care is taken, analysis run on several 1D-SDS gels are comparable. Further, the overall BBM preparation protocol (including a precipitation stage, several low/high spin centrifugation steps and many washes) appeared to be very stable and reproducible since the variability on the number of commonly identified proteins was in the same range as what was obtained with the BBM pool preparation loaded on the different gel variation and quite close to injection replicates. Finally, the comparison of panel E with panels C and D allow to draw some conclusions about the importance of a proper design of experiment to restrict unwanted variability. The major difference between those two conditions was that the LC-MS analysis performed for the panels C and D were purposely done using the same column and same buffer batch within the same sample measurement, whereas the LC-MS analysis performed for the panel E was done in a random order with sometimes column and buffer changes between the samples to be compared. Thus, the relative total variability increase observed for band 2 (see figure 4.22, panel E) was less than observed within band 9 (see figure 4.23, panel E) or 11 (see figure 4.24, panel D) because the three samples of band 2 were randomly analyzed however using the same column (additional variability might have been possibly due to the column history). The total variability for the band 9 was still moderate since there was only column change between the analyzed samples while the variability for band 11 was much higher, probably due to change of column and buffer between injections of the samples. This particular topic will be investigated more extensively in the next section. Interestingly, while band 2 was much more intense than bands 11 and 9 (the band 9 was very faint), the number of proteins identified in band 9 was double compared to band 2. This might be due in part to ion suppression due to very high abundant proteins in the band 2 (The instrument's duty cycle was limitating) and/or it might point to the presence of proteolytic fragments in this lower molecular mass band.

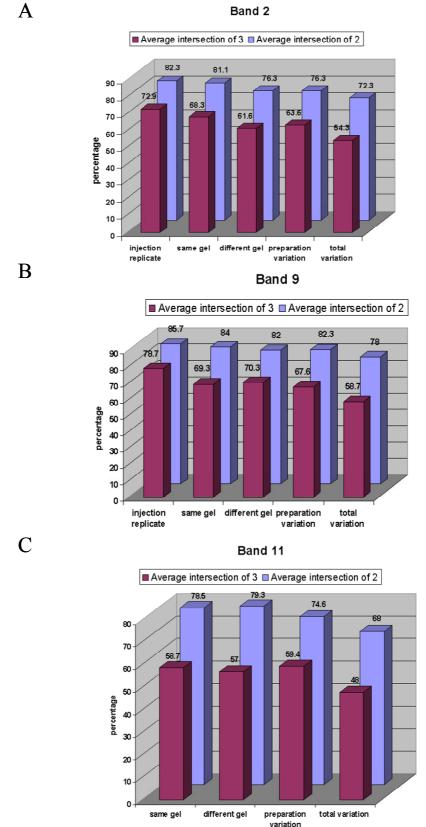

Figure 4.25: Graphic representation of Average intersections of 2 and 3 samples in each technical step for band 2 (Panel A), band 9 (Panel B) and band 11 (Panel C).

### 4.5.3.2 Estimation of experimental reproducibility based on LC-MS signals

Comparison of samples based on protein identification is a very well known and accepted practice in a proteomics experiment. Its main drawback lies in the fact that protein identification is based on properly annotated and identified MS/MS data corresponding to at most 10-20% of the overall mass spectrometric information due to the duty cycle and the sensitivity of the instrument. In other words, 80% of the generated information cannot be directly used, because either the MS/MS spectrum could not be successfully assigned to a peptide sequence or because the parent mass observed in the full MS spectrum was not selected for tandem MS analysis.

Recently, several groups (including ours) have started to consider the precursor ion intensity in the full spectrum as a more comprehensive descriptor for sample comparison. In this spirit, the data analysis performed at the peptide identification level was extended to include the MS precursor level. The variability of the BBM sample preparation and the influence of various technical parameters on the comparability of the samples were assessed to study how these can be directly derived at the MS level. Furthermore, the question on how much the information at the MS and the MS/MS levels corresponded was also explored.

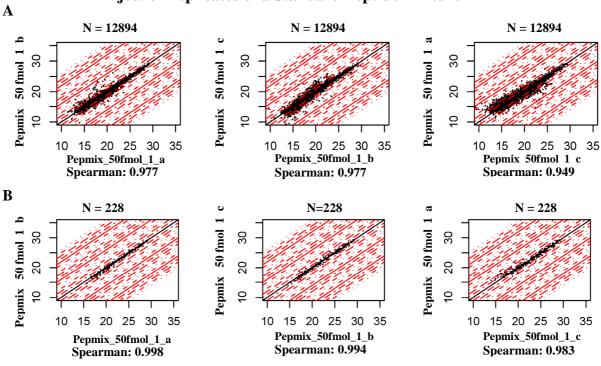

#### 4.5.3.2.1 Comparative analysis of a standard peptide mixture

In a first approach, a simple standard peptide mixture of 6 digested proteins Cytochrome C, Lysozyme, Alcohol dehydrogenase, Bovine serum albumin, Serotransferrin and ß-Galactosidase, (the so-called LCP Dionex peptide mixture) was used to tune the data processing scheme and to become acquainted with the data behavior in ideal settings to understand how to judge (dis)similarity in this context. The simplistic nature of this sample makes it significantly easier to monitor the dilution effect and column or buffer variability. In a second step, the key learning from this idealized study was applied to a more complicated dataset, such as the bands 2, 9 and 11 that have been discussed in the preceding section.

The raw data of each LC-MS run was processed according to the parameters described in § 3.2.7.3. Filtered signals that were present in 2/3 of the runs analyzed were accepted as common signals. Each of those MS signals was associated with a run-specific RT and accurate mass to allow the pairwise comparison of the processed MS signals between two samples in the form of scatter plots. The linearity and data distribution at the diagonal (that is, the intensity deviation of the common signals from an ideal linear relationship) was expressed using the Spearman correlation. Spearman's rank correlation coefficient is a non-parametric measure of correlation – that is, it assesses how well an arbitrary monotonic function could

describe the relationship between two variables, without making any assumptions about the frequency distribution of the variables. In the case of perfect reproducibility, we expect all the data points to be located in a diagonal, which gives a correlation of 1.0.

Fig. 4.26 shows the scatter plots representative for the comparison of three injection triplicates of a 50 fmol standard peptide mixture.

## **Injection replicates of a Standard Peptide Mixture**

Figure 4.26: Scatter plot representations of three injection replicates of a 50 fmol Standard Peptide Mixture. Panel A: Scatter plots of all common MS signals found in the three replicates. Panel B: Scatter plots of common MS signals which have been successfully assigned to a MS/MS identification. N states for the number of common signals. The Spearman value reflects the similarity of the signal intensities between the compared samples (ideal case Spearman correlation=1). Each red dot line parallel to the diagonal represents a two fold difference, i.e. across three lines, the fold change is 2\*2\*2=8. Accordingly, the axes represent an arbitrary mass spectrometric intensity (in counts) in log2 units.

The scatter plots for each compared LC-MS(/MS) pair, based on the total MS signals (Panel A) or the successful MS/MS measurements (Panel B), highly correlated with each other. The clustering of the common features along the diagonal indicates that the precursor MS ions have the same intensity in the two considered samples, a feature to be expected in this experiment where replicates injections of the same sample were analyzed. Further, the Spearman correlation values for both types of analyses were almost identical, strengthening our conviction that a comparison of samples based on the precursor mass intensity should provide comparable results as using the protein identification descriptor.

Scatter plots as shown in Fig. 4.26 could also be used to visualize dilution effects. For example, as shown in Fig. 4.27, the precursor mass signal intensity of a 50 fmol standard peptide mixture is compared to the precursor mass signal intensity of a 125 fmol injection of the same peptide mixture.

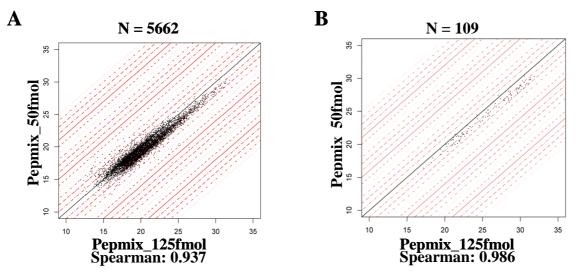

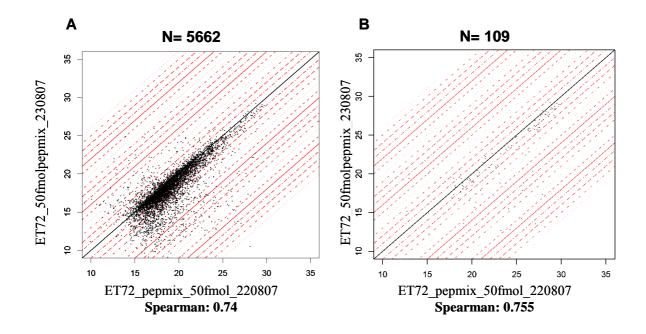

Figure 4.27: Scatter plot representations of a comparison between a 125 fmol and a 50 fmol injection of a Standard Peptide Mixture. Panel A: Scatter plots of all the common MS signals between the samples. Panel B: Scatter plots of the MS Signals that correspond to successful MS/MS measurements. N is the number of common signals. The Spearman value reflects the similarity of the signal intensities between the compared samples (ideal case Spearman correlation=1). Each red dot line parallel to the diagonal representss a two fold difference, i.e. across three lines, the fold change is 2\*2\*2=8. Accordingly, the axes represent an arbitrary mass spectrometric intensity (in counts) in log2 units.

The 109 common precursor mass intensities based on MS/MS identification (Fig. 4.27, panel B) all clearly lied on a diagonal with an offset of approximately 2.5 fold difference from unity, as was expected from the experiment design. A similar pattern could also be observed for the 5662 common precursor masses found in both samples (Fig. 4.27, panel A) with the exception that two ions populations were clearly detected. The first population, comprising the most abundant ions of the analysis, were lying on a diagonal with an offset of approximately 2.5 fold difference similarly to the ions that were identified through a MS/MS identification. This first population was assumed to represent actual peptides that were differentially detected in the analysis. The second ion population, which included mostly low abundant signal, clustered along the diagonal, and could represent the consistent chemical noise that was co-analyzed with the samples.

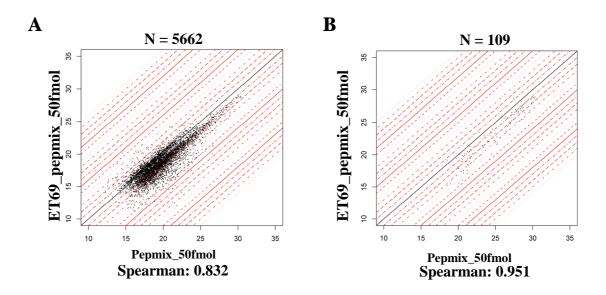

More subtle effects, such as column ageing, could also be monitored using the same strategy. The effect of column history on MS signal intensity was put in evidence by following the pattern of a 50 fmol standard peptide mixture analyzed in a new column and then again using the same column and LC buffers after several samples injections (Fig. 4.28).

**Figure 4.28:** Scatter plot representations of two 50 fmol injections of a Standard Peptide Mixture, injected onto the same column with the interval of several samples. Panel A: Scatter plots of all the common MS signals between the samples. Panel B: Scatter plots of the MS Signals that correspond to successful MS/MS measurements. N is the number of common signals. The Spearman value reflects the similarity of the signal intensities between the compared samples (ideal case Spearman correlation=1). Each red dot line parallel to the diagonal represents a two fold difference, i.e. across three lines, the fold change is 2\*2\*2=8. Accordingly, the axes represent an arbitrary mass spectrometric intensity (in counts) in log2 units.

Not surprisingly, the common signals of the two identical peptide standards did not show the same intensity. MS signals were stronger when the fresh standard peptide mixture (ET\_pepmix\_50fmol\_220807) was analyzed with a new column (for more details see appendix B: table of process variation time record). A Spearman correlation value of 0.74 for the total MS signals, or 0.755 for the MS signals with successful MS/MS identification, were significantly lower that for an ideal case, and demonstrated that column history might contribute to the experimental variability of comparable samples.

The impact of changing column and/or buffers during samples measurement was also investigated. The comparison of standard peptide mixtures measured using two identical columns (identical dimensions, lot number and sample history) showed that common MS signal intensities deviated somehow from the diagonal, also reflected in the lower Spearman correlation value (Fig. 4.29), but without dramatic changes in the data behavior.

**Figure 4.29:** Scatter plot representations of two 50 fmol injection of a Standard Peptide Mixture, injected in two identical columns with the same sample history. Panel A: Scatter plots of all the common MS signals between the samples. **Panel B:** Scatter plots of the MS signals that correspond to successful MS/MS measurements. N is the number of common signals. The Spearman value reflects the similarity of the signal intensities between the compared samples (ideal case Spearman correlation=1). Each red dot line parallel to the diagonal represents a two fold difference, i.e. across three lines, the fold change is 2\*2\*2=8. Accordingly, the axes represent an arbitrary mass spectrometric intensity (in counts) in log2 units.

A similar data distribution was observed when the standard peptide mixture was analyzed on the same column but using different LC solvent batches (results not shown). However, these two effects acted synergistically when the standard peptide mixture was analyzed using different columns and different LC buffer batches (Fig. 4.30), as reflected by the lower Spearman correlation values. Interestingly, the column/buffer effects were consistently more pronounced at the global precursor MS level than at the common signals that were linked to a successful MS/MS measurement. However, the limited number of measurements that were performed using the standard peptide mixture did not allow to differentiate whether this difference in distribution was mostly due to a massive change of background ions distribution compared to the peptide signals, or whether the difference was due to minor mismatching of the precursor masses during sample analysis, leading to increased noise in the corresponding scatter plots.

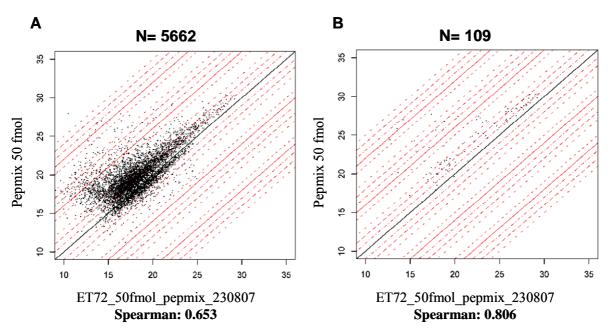

Figure 4.30: Scatter plot representations of two injections of a 50 fmol Standard Peptide Mixture onto two different columns and using different buffers batches. Panel A: Scatter plots of all the common MS signals between the samples. Panel B: Scatter plots of the MS signals that correspond to successful MS/MS measurements. N is the number of common signals. The Spearman value reflects the similarity of the signal intensities between the compared samples (ideal case Spearman correlation=1). Each red dot line parallel to the diagonal represents a two fold difference, i.e. across three lines, the fold change is 2\*2\*2=8. Accordingly, the axes represent an arbitrary mass spectrometric intensity (in counts) in log2 units.

In summary, the analysis of a simple standard peptide mixture using idealized differential conditions of the LC-MS system confirmed that the precursor ion intensity embodies an appropriate descriptor to evaluate the similarity of a sample to another and to pinpoint to common experimental deviations, such as column and LC buffer changes, or dilution effects. In particular, the behavior of all the ions considered in a pair of samples was very comparable to the ion population that was characterized by tandem mass spectrometry to represent the mass spectrometric signals of peptides commonly shared by the two samples considered.

The quality of this similarity was expressed using the Spearman correlation value, a nonparametric function to evaluate the degree of correlation between two parented ion intensity population to follow an arbitrary monotonic function, here a simple linear function of slope x=1. It is of interest that the Spearman correlation value was calculated here taking into account all the ions considered. However, the graphic representation of the ion distribution in the form of scatter plot clearly separated two populations of ions. The first group mostly clustered at the diagonal independently of the samples being compared and tended to encompass the lower intensity ions. The second group, which included mostly the higher intensity ions, also clustered along a diagonal but with a distinct offset from the first group depending on the type of samples being compared. It was our belief that these two groups represented the solvent and LC contaminants ions and the sample peptide ions, respectively, which should be considered separately in an ulterior version of this similarity measure.

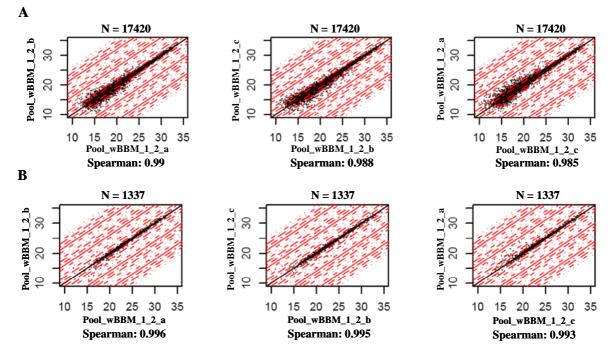

## 4.5.3.2.2 Comparative analysis of the BBM SDS gel bands 2, 9 and 11.

The quality and the reproducibility of the BBM preparation was assessed at the precursor ion level on the basis of the analysis of the selected gel bands 2, 9 and 11. The goal of this analysis was two-fold: firstly, to explore whether a differential analysis based on precursor mass intensities would align with the findings derived from the comparison of the same samples based on protein identification; and secondly, to evaluate to which extent the (ir)reproducibility of the LC-MS system could be observed in a more complex protein mixture such as used for the BBM identification study.

As already mentioned in section 4.5.2, all comparisons were performed using three representative SDS-PAGE bands, Bands 2, 9, and 11. Band 2 represented a very abundant, very well defined high molecular mass band (expectation: excellent reproducibility) while Band 9 represented a diffuse, very faint band (expectation: not so good reproducibility). Band 11 also displayed a well defined band but differed from Band 2 by the fact that the proteins present in the mass range of the gel might also encompass proteolytic products (expectation: average reproducibility). For simplicity reason, only representative scatter plots of chosen sample comparisons will be shown. The complete set of scatter plots and Spearman correlation values for all comparisons can be found in appendix B3.

Fig. 4.31 shows the comparison scatter plots for the three injection replicates of the band 2. The three replicates were very reproducible according to the scatter plot representation of all common MS signals and of the MS signals that correspond to successful MS/MS measurement. The Spearman correlation values for all comparisons were above 0.98 underlining the very good linearity of the signals at the diagonal. Similarly to what was observed with the simple Dionex protein mixture, the MS signals which were successfully assigned a peptide sequence through MS/MS analysis were in large of high signal intensity (panel B). However, this ion population represented less than 10% of the overall common MS signals (compare N between panel A and B).

#### **Injection replicates for band 2**

**Figure 4.31:** Scatter plot representations of the injection replicates of the band 2. Panel A: Scatter plots of all the common MS signals between the replicates. Panel B: Scatter plots of the MS signals that correspond to successful MS/MS measurements. N is the number of common signals. The Spearman value reflects the similarity of the signal intensities between the compared samples (ideal case Spearman correlation=1). Each red dot line parallel to the diagonal represents a two fold difference, i.e. across three lines, the fold change is 2\*2\*2=8. Accordingly, the axes represent an arbitrary mass spectrometric intensity (in counts) in log2 units. All sample denominations are as described in Fig. 4.21.

Further, the comparison scatter plots for a triplicate analysis of the band 2 excised from three adjacent SDS-PAGE lanes is shown in Fig. 4.32. The added variability of this technical step compared to the triplicate injection replicate was rather moderate as judged by the uniform and only slightly lower Spearman correlation values compared to the injection replicates. The main feature differentiating those two analyses were a broadening of the ion distribution along the diagonal, especially noticeable at the lower ion intensity scale, and a ion correlation matrix that did not include the least intense ion, probably because of lack of reproducibility (compare Fig. 4.31 and Fig. 4.32 panels A and panels B side by side). Interestingly, within the triplicate analysis included in Fig. 4.32, the samples pool\_wBBM\_2\_2 and pool\_wBBM\_3\_2 appeared to correlate slightly better to each other than with the sample pool\_wBBM\_2\_1, a finding that was not observed from the Venn diagrams analysis of the same samples (compare with Fig. 4.22, panel B).

#### Same gel variation for band 2

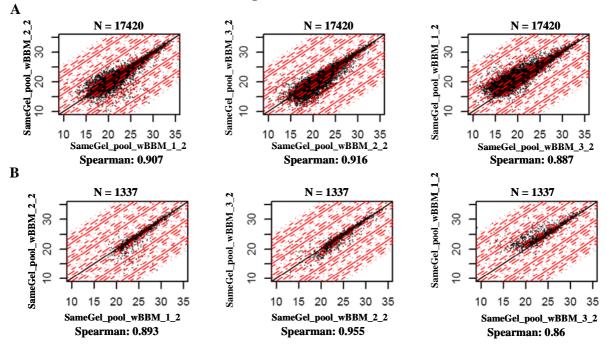

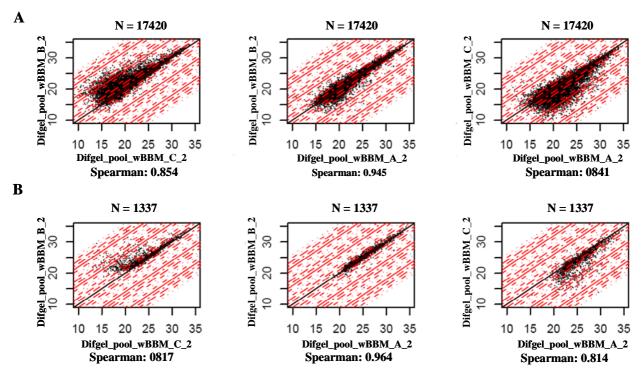

Figure 4.32: Scatter plot representations of the variability for the band 2, cut horizontally from adjacent identical lanes. Panel A: Scatter plots of all the common MS signals between the replicates. Panel B: Scatter plots of the MS signals that correspond to successful MS/MS measurements. N is the number of common signals. The Spearman value reflects the similarity of the signal intensities between the compared samples (ideal case Spearman correlation=1). Each red dot line parallel to the diagonal represents a two fold difference, i.e. across three lines, the fold change is 2\*2\*2=8. Accordingly, the axes represent an arbitrary mass spectrometric intensity (in counts) in log2 units. All sample denominations are as described in Fig. 4.21.

Similarly, the comparison scatter plots for a triplicate analysis of the band 2 excised from a lane run in three separate SDS-PAGE gels is shown in Fig. 4.33. As expected from the previous analysis, the added variability of this technical step was very comparable to the variability obtained from the triplicate bands excised from a single SDS-PAGE gel. The measurement reproducibility depended mostly on how accurately the bands were defined and excised from the SDS-PAGE gel, the type (wide/narrow; defined/diffuse, etc.) of bands that was analyzed, and how identically the gels to be compared had run. Interestingly, in this triplicate analysis shown in Fig. 4.33, the samples pool\_wBBM\_A2 and pool\_wBBM\_B2 appeared to correlate slightly better to each other than with the samples pool\_wBBM\_C2, a finding that was not observed from the Venn diagrams analysis of the same samples (compare with Fig. 4.22, panel C). Taken together, the results obtained in Fig. 4.32 and 4.33 suggest that the SDS-PAGE step appeared non-critical for the reproducibility of an experiment as long as the parameters for protein separation and band excision were kept tightly controlled.

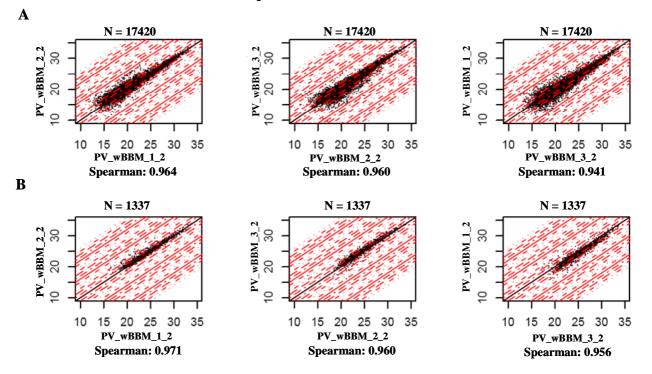

#### Different gel variation for band 2

**Figure 4.33:** Scatter plot representations of the band 2 from identical BBM samples, loaded in three different gels. Panel A: Scatter plots of all the common MS signals between the replicates. Panel B: Scatter plots of the MS signals that correspond to successful MS/MS measurements. N is the number of common signals. The Spearman value reflects the similarity of the signal intensities between the compared samples (ideal case Spearman correlation=1). Each red dot line parallel to the diagonal represents a two fold difference, i.e. across three lines, the fold change is 2\*2\*2=8. Accordingly, the axes represent an arbitrary mass spectrometric intensity (in counts) in log2 units. All sample denominations are as described in Fig. 4.21.

The comparison scatter plots for the LC-MS signals of the band 2 originating from three different technical BBM preparations is shown in Fig. 4.34. Since all technical steps (samples run on the same SDS-PAGE gel, band excision, digestion, column and buffer batch, LC-MS conditions) were maintained constant, the observed variability for the common signals should mainly reflect the reproducibility of the BBM preparation. The common MS signals (Panel A) and the common MS signals that were assigned to a successful MS/MS identification (Panel B) were clustered at the diagonal indicating a high level of similarity between the three BBM preparations. This observation was supported by a high Spearman correlation value (above 0.94) for all the comparisons. This high degree of reproducibility was also noted for the preparation variation analysis of bands 9 and 11 (results not shown, for more details see appendix B) and correlated with the findings obtained from the protein identification level (see Fig. 4.22, panel E, Fig. 4.23, panel E and Fig. 4.24, panel D). These results demonstrate

that the BBM preparation protocol could be performed in a very stable and reproducible manner that added only a minimal variability compared to other technical steps.

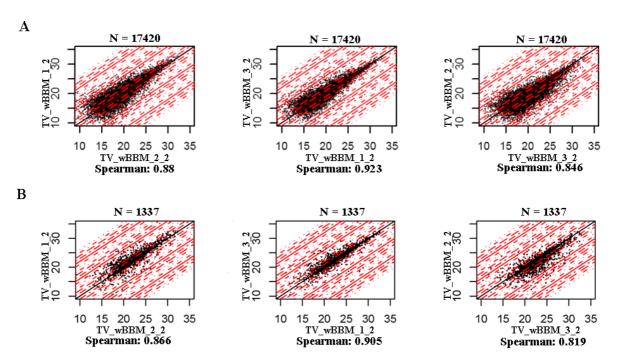

Preparation variation for band 2

Figure 4.34: Scatter plot representations of the preparation variability for the band 2 from three BBM technical replicate preparations. Panel A: Scatter plots of all the common MS signals between the replicates. Panel B: Scatter plots of the MS signals that correspond to successful MS/MS measurements. N is the number of common signals. The Spearman value reflects the similarity of the signal intensities between the compared samples (ideal case Spearman correlation=1). Each red dot line parallel to the diagonal represents a two fold difference, i.e. across three lines, the fold change is 2\*2\*2=8. Accordingly, the axes represent an arbitrary mass spectrometric intensity (in counts) in log2 units. All sample denominations are as described in Fig. 4.21.

Finally, the comparison scatter plots for the LC-MS signals of the band 2, 9 and 11 originating from three different technical BBM preparations is shown in Fig. 4.35, 4.36 and 4.37, respectively. In this last set of analyses, however, the technical steps were not as tightly controlled and the samples were analyzed in random orders.

According to the scatter plot representation and the Spearman correlation values (Fig. 4.35), the variability observed for the band 2 was considerably lower than for the bands 9 and 11. In this experiment, variability must originate from the technical steps since the three BBM preparation were found to be highly reproducible in the previous section. In our experience, most

of the technical variability was due to different column history, column and LC buffer changes

Total variation for band 2

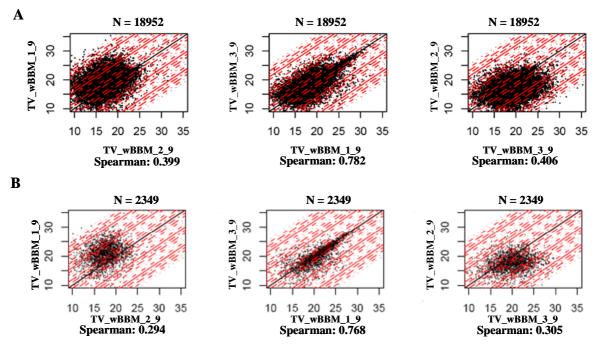

**Figure 4.35:** Scatter plot representations of the total variability for the band 2 from three *BBM technical replicate preparations, randomly analyzed. Panel A:* Scatter plots of all the common MS signals between the replicates. **Panel B:** Scatter plots of the MS signals that correspond to successful MS/MS measurements. N is the number of common signals. The Spearman value reflects the similarity of the signal intensities between the compared samples (ideal case Spearman correlation=1). Each red dot line parallel to the diagonal represents a two fold difference, i.e. across three lines, the fold change is 2\*2\*2=8. Accordingly, the axes represent an arbitrary mass spectrometric intensity (in counts) in log2 units. All sample denominations are as described in Fig. 4.21.

Indeed, the triplicates of the band 2 were randomly analyzed along the whole experiment but the column and LC buffer remained the same for the three analyses. The Spearman correlation value was slightly lower than was found for the preparation variation alone but remained in the same range. The slightly elevated variability could be due to the manner the gel bands were excised from the gel (one after the other versus horizontal parallel cutting) and to the LC column history. Thus, according to the Spearman correlation value, the samples TV\_wBBM\_3\_2 and TV\_wBBM\_2\_2 were significantly better correlated than with TV\_wBBM\_1\_2 probably, because these two first samples were analyzed very closely to each other at the LC-MS level (only 2 samples separated the two band 2 replicates).

The variability observed for band 9 was significantly higher than that found for band 2 and was reflected in the scatter plots and the Spearman correlation values (Fig. 4.36). In our experience, this large increase in variability was due to column and buffer changes during the

analysis of the band 9 triplicates. Thus, the correlation of the replicates TV\_wBBB\_1\_9 and TV\_wBBM\_3\_9 was much higher than with TV\_wBBM\_2\_9. TV\_wBBB\_1\_9 and TV\_wBBM\_3\_9 were analyzed on two different columns but using the same LC buffer batch, while TV\_wBBM\_2\_9 was analyzed using a different column and another LC buffer batch. More details about the analysis sequence of all the samples included in this experiment can be found in the process variation measurement times in the appendix B.

#### **Total variation for band 9**

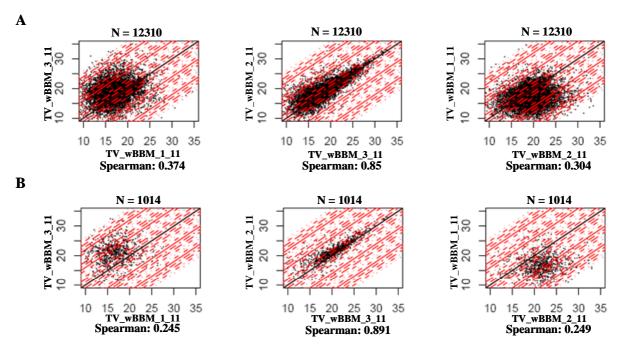

**Figure 4.36:** Scatter plot representations of the total variability for the band 9 from three *BBM technical replicate preparations, randomly analyzed. Panel A:* Scatter plots of all the common MS signals between the replicates. **Panel B:** Scatter plots of the MS signals that correspond to successful MS/MS measurements. N is the number of common signals. The Spearman value reflects the similarity of the signal intensities between the compared samples (ideal case Spearman correlation=1). Each red dot line parallel to the diagonal represents a two fold difference, i.e. across three lines, the fold change is 2\*2\*2=8. Accordingly, the axes represent an arbitrary mass spectrometric intensity (in counts) in log2 units. All sample denominations are as described in Fig. 4.21.

Column and buffer changes affected the analysis of band 11 in a similar fashion as seen in band 9 (see Fig. 4.37). Thus, the two replicates TV\_wBBM\_2\_11 and TV\_wBBM\_3\_11 clustered significantly better to each other than with the replicate TV\_wBBM\_1\_11. Indeed, the replicates TV\_wBBM\_2\_11 and TV\_wBBM\_3\_11 were measured using different columns but the same LC solvent batch, while TV\_wBBM\_1\_11 was analyzed using a different column and another LC buffer batch.

Interestingly, for all bands considered (but mostly for bands 9 and 11), the significantly lower comparability of the total variability analysis compared to the preparation variability analysis

was only partially observed at the protein identification level (see Fig. 4. 22, panel D and E; Fig. 4.23, panels D and E; and Fig. 4.24, panels C and D). The ion correlation matrix which

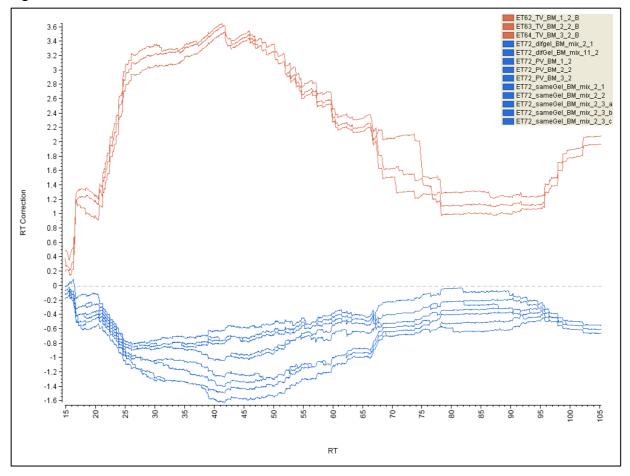

#### **Total variation for band 11**

**Figure 4.37:** Scatter plot representations of the total variability for the band 11 from three *BBM technical replicate preparations, randomly analyzed. Panel A:* Scatter plots of all the common MS signals between the replicates. **Panel B:** Scatter plots of the MS signals that correspond to successful MS/MS measurements. N is the number of common signals. The Spearman value reflects the similarity of the signal intensities between the compared samples (ideal case Spearman correlation=1). Each red dot line parallel to the diagonal represents a two fold difference, i.e. across three lines, the fold change is 2\*2\*2=8. Accordingly, the axes represent an arbitrary mass spectrometric intensity (in counts) in log2 units. All sample denominations are as described in Fig. 4.21.

was used to create the scatter plots depends heavily on a reproducible RT and m/z parameters linked with the measured ion signal intensity, whose variability was minimized by measuring the samples to compare immediately one after another. Moreover, the correlation matrix took into account all MS signals that were commonly assigned to the samples, with a majority of them being rather of low intensity and subject to higher variability. In contrast, sample comparison by protein identification was based on a MS signal that was successfully assigned to an amino acid sequence through a MS/MS identification. Since this ion population comprised mostly well behaved, reproducible high intensity MS signal, the correlation matrix illustrated through Venn diagrams was much more resistant to intensity variability than for the common MS signals.

## 4.5.3.2.3 LC-MS reproducibility

The total variability analysis for the bands 9 and 11 showed that a major part of the observed technical variability was caused by the LC buffer followed by the column changes. Buffer changes, in particular, had a major impact on the peptides' retention times as shown in the figure 4.38 and 4.39.

**Figure 4.38:** Genedata Refiner MS signals representation of the retention time (RT) alignments of all the technical replicates related to band 2. The RT alignments of the total variation (TV) samples are marked in red while all other technical replicate samples are marked in blue. The two sample groups cluster according to the LC buffer and column batch they had been analyzed with, see text for additional details. The name conversion for the data files in the inset can be found in appendix B.

The retention time alignment for the band 2 and 11 showed the obvious impact of LC buffer and column change on the MS signal alignment. In the case of band 2 (see figure 4.38) the RT alignment of the three "total variation" sample replicates (red traces) aligned very well with each other because these samples were analyzed using the same column and buffer batch. A similar good alignment was observed for all remaining LC-MS measurements (blue traces) of the band 2 as they were also measured using the same column and buffer batch. In this particular example, the rather different behaviors of both sample sets was due to the use of different column and LC buffer batches, resulting in a less satisfying alignment between the common MS signals.

The picture was somehow different for the RT alignment of the band 11. The MS signals of the samples TV\_wBBM\_2\_11 and TV\_wBBM\_3\_11 showed very good RT alignments (Figure 4.39, red traces) to each other, although they were analyzed with two different columns. On the other hand, the RT coordinates from the third triplicate TV\_wBBM\_1\_11 appeared to significantly deviate from the two other MS signals (see figure 4.39, green traces) due to a buffer change between the analysis of this sample and the other two replicates. Finally, all remaining LC-MS measurements (blue traces) of the band 11 were measured using the same column and buffer batch, thus showing a consistent RT alignment with each other.

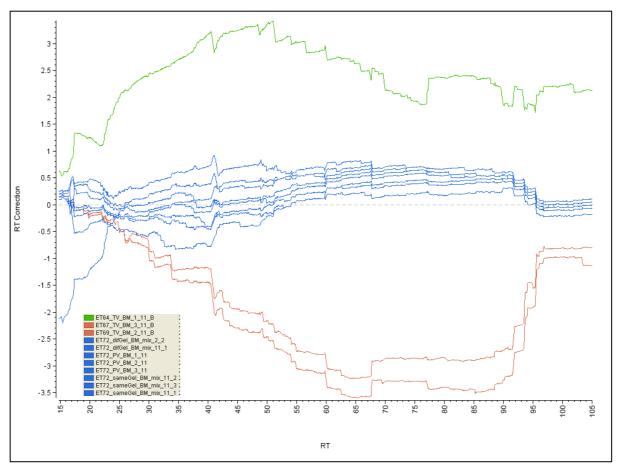

Figure 4.39: Genedata Refiner MS signals representation of the retention times (RT) alignments of all the technical replicates related to band 11. The RT alignments of the total variation (TV) samples are marked in red and green while all other technical replicate samples are marked in blue. The three sample groups cluster according to the LC buffer and column batch they had been analyzed with, see text for additional details. The name conversion for the data files in the inset can be found in appendix B.

#### 4.5.3.3 Findings and discussion

Many researchers in the field have claimed that the LC-MS/MS approach lacks the technical reproducibility to reliably identify proteins in a proteomics experiment. In this study, we aimed to examine this common belief by setting up an experiment in which we evaluated the reproducibility of the LC-MS measurements by counting how many proteins could reliably be identified in the analysis of triplicate technical BBM preparations.

The triplicate LC-MS/MS measurements of the 19 gel bands corresponded to each BBM preparation (see § 4.2) resulted in almost 90% commonly identified proteins in at least two of three preparations with at least two different peptides in one of the reprlicates. This degree of reproducibility was much higher than what was optimistically expected in our group and better than what has been openly claimed so far by other proteomics groups.

This unexpected outcome led me to investigate in more details whether this very high level of identification reproducibility achieved in this study was not based on an over-optimistic interpretation of the data. For this reason I decided to study in a systematic manner the contribution in variability that selected technical steps might add in the overall analytical process. For this purpose, the gel bands 2, 9 and 11, and a standard peptide mixture were used as references to set up an experiment to monitor the variability of the LC-MS(/MS) system (mass spectrometer performance, column history and column or/and buffer change), the gel band excision process, and the variations due to the BBM isolation protocol.

Data analysis and interpretation proved to be a very hard and time consuming process, because there was no unique value to comprehensively report on the simultaneous comparison of three (or more) samples. One of the main reasons to adopt the Venn diagram representation was that the commonly identified proteins within the triplicate analysis could be easily visualized. Simultaneously, we sought to take advantage of the high mass accuracy provided by the Orbitrap mass spectrometer and the reproducibility of the liquid chromatographic system to evaluate, whether such a data analysis could also be performed using the precursor mass intensity.

Taken as a whole, the systematic evaluation of the technical variability added by selected technical steps to the overall analytical process unambiguously confirmed the high reproducibility achieved by the LC-MS/MS process at the protein identification level. As expected, sample comparison based on injection replicates showed the best reproducibility, stressing the stability and the robustness of the LC-MS/MS system. The strategy used to excise bands from SDS-PAGE gels (horizontally in adjacent lanes of the same gel, or one lane

cut after the other on different gels) was identified to potentially represent a major cause of variability if not appropriately controlled. An irreproducible gel excision pattern might cause a considerable variability in the protein content of a given gel band leading to inconsistent identifications when compared to the equivalent gel band of another sample.

The BBM isolation protocol itself was a potential source of variability due to its relative length and complexity and due to the inclusion of several steps that might have been difficult to carry out quantitatively, such as the CaCl<sub>2</sub> precipitation step. Also, the remaining proteolytic activity of the abundant BBM proteases, if unchecked, could also contribute to sample degradation and add extensive variability to the protein identification process. The preparation variation as mirrored in the comparison of the BBM technical triplicate analysis of bands 2, 9 and 11 showed a very high level of reproducibility in the number of commonly identified proteins (almost at the level of injection replicates) as long as all other technical steps (SDS-PAGE gel, band excision strategy, LC-MS/MS conditions) were kept constant. The variability in the number of commonly identified proteins was significantly higher when the samples were analyzed without a design of experiment. Thus, the number of proteins commonly identified in the three technical replicates of band 2 was rather similar in the preparation variation study (all technical steps were controlled) and in the total variation study (analysis without design of experiment) while the number of commonly identified proteins in the technical replicates of band 9 and 11 was significantly lower in the total variation study compared to the preparation variation study. One of the main reasons for this differences is believed to be due to column and buffer changes during the analysis of the bands 9 and 11 samples, while the analysis of the band 2 samples were performed using the same column and buffer batch.

The degree of variability added by each technical step and by the BBM preparation protocol was also investigated at the full MS signal level. The comparative analysis of the precursor ion signals might provide additional information on sample similarity, since data comparison at the protein identification level (using successful MS/MS signals) makes use of only 10% of the total available signals. On the other hand, the sample similarity information that was derived from the MS/MS-based comparison must also be detected at the precursor ion signal intensity level. Overall, the scatter plot representations of the total MS signals and of the subset of MS signals that were identified through a successful MS/MS analysis correlated well with each other across all compared samples. Moreover, the derived Spearman correlation value, which indicated the degree of similarity between two samples, showed the same trends as what was observed using the Venn diagram representations. Thus, the scatter

plots representations and the associated Spearman correlation values also confirmed the very high degree of reproducibility observed between sample injection replicates, as previously shown at the protein identification level. Likewise, the gel band excision scheme was also identified as a potential source of variability, if gel bands could not precisely be cut from the gel, as for example in the case of band 11. Finally, the preparation variation study, as reflected in the scatter plots and the Spearman correlation values for all the three bands, showed also a high degree of reproducibility, strong evidence that the BBM preparation protocol could be performed robustly and quantitatively, if all technical steps were controlled. An unexpected finding of this systematic study was the large impact of LC buffer change on the analytical variability. This effect was best illustrated in the total variation study of band 11, where in one of the three triplicates clearly deviated from the two other samples. The MS signal alignment of those three samples showed clearly the major shift of the peptides' retention time caused by the LC buffer change. In contrast, column change did not appear to contribute significantly to the overall technical variability, as minor column backpressure heterogeneities were compensated by the HPLC system's active flow splitter system (the LC system measures the actual flow going through the column, meaning that the LC column pressure is adjusted to keep the linear velocity constant through the column).

In summary, it is apparent that sample comparison based on protein identification or on precursor ion signals were inherently similar. However, it is obvious that the optimized use of the mass spectrometric information will heavily depend on the generation of reproducible experimental data following a standard operating procedure. As a general rule, samples that should be compared to each other should be analyzed with identical column and buffer batches. In cases where this is not feasible, it is very important that buffers and columns are reproducibly and accurately prepared. The repeated analysis of a standard complex peptide mixture along the experiment and after any changes of buffer or/and column allow to monitor the variation of the peptides' retention time and to judge the "good health" of the chromatographic system. However, even in an optimal experimental setting, comparison of serially acquired LC-MS(/MS) data will require the development of bioinformatics tools attuned to this specific data type. As highlighted in this study, one of the most immediate tasks to perform in a differential study is to measure the level of variability present in a given analysis, which in turn defines the criteria of acceptance for a reproducibly observed signal. The assessment on how to define such a signal, including the noise and variability introduced by the various technical steps of the analytical protocol, has been one of the most challenging

problem in data analysis of proteomics experiments, but also central to determine to which degree a signal difference can be confidently interpreted as a real change.

This study constitutes the first attempt of our group to compare biological samples using the precursor ion intensity information. In due course, this first step was to be followed by a full fledge proteomics study in which a much more comprehensive biological experiment could have been investigated, such as a control mouse vs statins vs ezetimibe treatment, knowing in advance the level of technical reproducibility that could be expected. Beside the obvious biological interest for such a study (the impact of those drugs in the BBM has not been investigated in detail), a long term goal of this experiment could have been to evaluate the feasibility of a label-free quantification scheme based on the common precursor ion signals. In this approach, every peptide signal within the sensitivity range of the MS analyzer can be extracted and incorporated into the quantification process independently of a MS/MS acquisition. In a first step, data acquisition is performed using a high resolution/high mass accuracy mass spectrometer using a stable chromatographic system to generate the most stable <m/z;RT;ion intensity> possible applying the analytical principles that this initial study helped to uncover. In a second step, the identity of the differentially regulated proteins is achieved using a targeted tandem mass spectrometry analysis approach using for example inclusion lists in selected LC-MS runs (78, 117, 118).

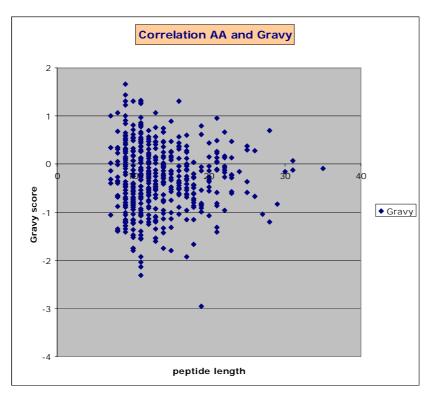

# 4.6 Peptide identification by LC-MS/MS

The reliable identification of membrane proteins in complex biological mixtures has always been a grey area in the proteomics field. As exemplified in this study, the contamination of even small amounts of cytosolic proteins in membrane preparations might significantly impede the identification of membrane proteins, especially if they are present in low abundance. The difficulties to obtain a high coverage of membrane proteins in biological preparations are several-fold: first, the biochemical enrichment of membrane proteins typically requires an extensive knowledge of the cell compartment to isolate, so to improve the yield in membrane proteins. However, optimized isolation protocols are not easily adjustable for other biochemical applications, so that most preparations do not achieve a level of purity sufficient for optimal detection of membrane proteins. Second, membrane proteins are by nature averse to most protein chemical purification methods (with maybe the exception of SDS-PAGE) and special care has to be taken to prevent their loss during the isolation protocol. Finally, membrane proteins are chemically composed of very hydrophobic stretches that, upon proteolytic cleavage, might not generate peptides detectable by mass spectrometry.

In general, it is not possible to specifically attribute the reasons for the limited success of a proteomics study to identify membrane proteins. However, since the BBM isolation protocol described in this study generated a preparation of highly enriched membrane proteins in complex mixture, there was a golden opportunity to investigate the nature, and more specifically, the length and the hydrophobicity of membrane proteins' peptides that were identified using a standard RPLC-ESI-MS/MS setup (with a LTQ mass spectrometer as mass analyzer).

# **4.6.1** Characteristics of identified peptides

For the purpose of this investigation, only the 663 identified tryptic peptides that were derived from 35 confirmed transmembrane BBM proteins were considered for subsequent analysis. First, the GRand AVerage of hydropathicitY (GRAVY) was manually calculated for each the ProtParam tool available at web peptide using Expasy site (http://www.expasy.org/tools/protparam.htmlsequences). The GRAVY value is calculated as the sum of hydrophathy values of all the constituting amino acids divided by the number of residues in the sequence(119) and reflects somehow the hydrophobicity of a protein or a peptide. Fig. 4.40 shows a two-dimensional graphic representation linking the GRAVY scores and the amino acid lengths of the 663 identified tryptic peptides, assuming that the GRAVY score calculation can also be applied to peptides. Tryptic peptides containing methionine oxidation were excluded while cysteines were assumed to be in reduced form.

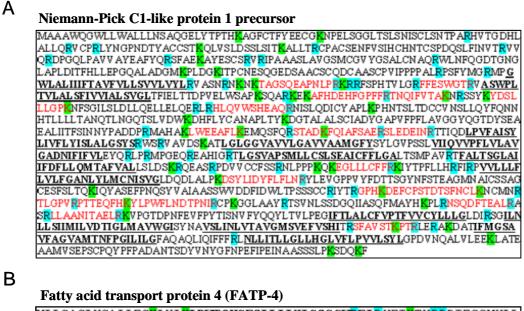

**Figure 4.40:** *Two-dimensional representation linking the GRAVY scores with the peptide amino acid length for the 663 identified tryptic peptides. Tryptic peptides containing methionine oxidation were excluded while cysteines were assumed to be in reduced form.* 

For convenience, peptides with GRAVY values above 0.5 will be referred to as hydrophobic, those with GRAVY values below -0.5 as hydrophilic, while the remainder will be considered to be of medium character. Peptides distribution in the GRAVY scores was remarkably symmetrical with a slight tendency to negative values. Most of the identified peptides were of medium character and were less than twenty amino acids of length. There was a small number of hydrophobic peptides with GRAVY score values above 1, but those very hydrophobic peptides were typically short, i.e. between 10 and 15 amino acids long.

# **4.6.2** Comparison of identified peptides with predicted tryptic transmembrane peptides

In a next step, the position of the 663 identified tryptic peptides were determined in the 35 protein sequences in the dataset and compared to the location of transmembrane segments, as predicted by the TMHMM software. Fig. 4.41 shows two examples for representative integral BBM membrane proteins. The first example, the Nieman Pick C1-like protein 1, was one of the most abundant membrane proteins in the BBM preparation. This protein was predicted to possess 13 transmembrane helices and was identified with 16 different peptides. The second example, the FATP-4 protein, was a protein of rather low abundance in the preparation. It was predicted to possess 2 transmembrane helices and was identified with 2 different peptides.

MLLGASLVGALLFS<mark>K</mark>LVL**KLPWTQVGFSLLLLYLGSGGWRFIR**VFIKTVRRDIFGGMVLL KVKTKVRRYLQERKTVPLLFASMVQRHPDKTALIFEGTDTHWTFRQLDEYSSSVANFLQA RGLASGNVVALFMENRNEFVGIWLGMAKLGVEAALINTNLRRDALRHCLDTSKARALIFG SEMASAICEIHASLEPTLSLFCSGSWEPSTVPVSTEHLDPLLEDAPKHLPSHPDKGFTDK LFYIYTSGTTGLPKAAIVHSRYRMASLVYYGFMRPDDIVYDCLPLYHSAGNIVGIGQ CLLHGMTVVIRKKFSASRFWDDCIKYNCTIVQYIGELCRYLLNQPPREAESRHKVRMALG NGLRQSIWTDFSSRFHIPQVAEFYGATECNCSLGNFDSRVGACGFNSRILSFVYPIRLVR VNEDTMELIRGPDGVCIPCQPGQEQLVGRIIQQDPIRRFDGYLNQGANNKKIANDVFKK GDQAYLTGDVLVMDELGYLYFRDRTGDTFRWMGENVSTTEVEGTLSRLLHMADVAVYGVE VPGTEGRAGMAAVASPISNCDLESFAQTLKKELPLYARPIFLRFLPELHKTGTFKFQKTE

**Figure 4.41:** Amino acid sequence of two representative integral transmembrane BBM proteins. Panel A: Niemann-Pick C1-like protein 1, and Panel B: Fatty acid transporter protein 4. Lysines (K) and arginines (R) are highlighted in green and blue, respectively. Identified tryptic peptides are marked in bold red while the predicted location of transmembrane helices is underlined and marked in bold.

Fig. 4.41 clearly shows that none of the identified tryptic peptides were located in the transmembrane helices, but rather within the loops (NPC1L1) or in the large cytoplasmic region of the protein (FATP-4).

Further, the hydropathicity of the predicted 228 transmembrane tryptic peptides belonging to the 35 integral membrane BBM proteins was calculated using the ProtParam tool. Fig. 4.42 shows a histogram comparing the amino acid lengths (panel A) and GRAVY scores (panel B) for the 663 identified tryptic peptides versus the 228 predicted tryptic transmembrane peptides. Not surprisingly, the vast majority of the identified tryptic peptides were much shorter and less hydrophobic than the predicted tryptic transmembrane peptides. However, according to these data, the two groups of peptides somehow overlap indicating that a small number of predicted transmembrane peptides should have been identified using the generic LC-MS conditions that were used in this experiment.

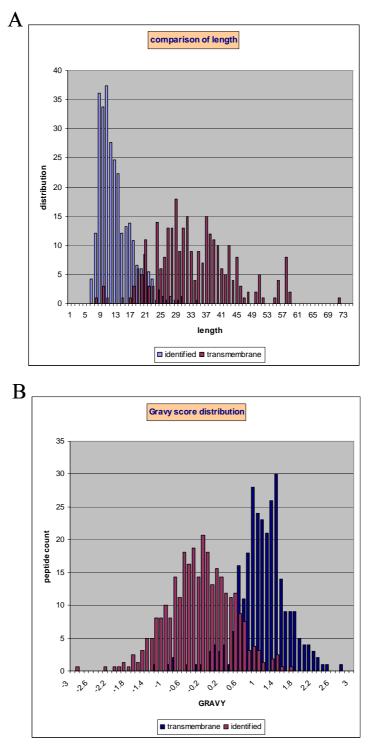

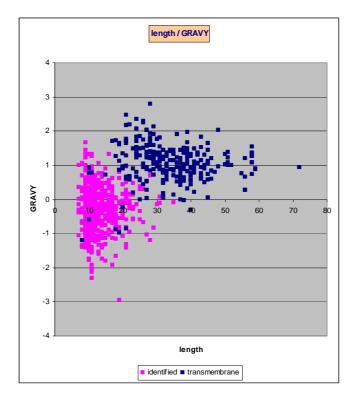

Figure 4.42: Histogram of the amino acid length (Panel A) and hydropathicity (Panel B) for the 663 identified tryptic peptides versus the 288 predicted tryptic transmembrane peptides derived from the 35 identified transmembrane proteins. The identified tryptic peptides are marked in red while the predicted transmembrane tryptic peptides are marked in blue. The total number of peptide counts was normalized.

Fig. 4.43 shows a two-dimensional view of the two histograms of Fig. 4.42 linking the GRAVY scores with the amino acid lengths for the identified tryptic peptides and the predicted tryptic transmembrane peptides.

**Figure 4.43:** Two-dimensional representation linking amino acid length and GRAVY scores for the 663 identified peptides and the 228 predicted transmembrane tryptic peptides. The observed tryptic peptides are marked in pink, the predicted tryptic transmembrane peptides in blue.

Fig. 4.43 clearly confirms that the identified tryptic peptides were, in average, much shorter and somewhat less hydrophobic than their predicted tryptic transmembrane counterparts. It is evident that the GRAVY score was not discriminative to explain the lack of identification of those predicted transmembrane tryptic peptides. Indeed, a number of observed tryptic peptides bear a GRAVY score of 1 or above similarly to the predicted transmembrane tryptic peptides. Rather, the average length of the typical predicted transmembrane peptide seems to separate best the two populations. However, an overlap between those two peptides populations remains, with GRAVY values between 0 and 1 and peptide lengths between 20 and 30 amino acids, which strongly suggest that identification of at least a few of those transmembrane tryptic peptides should have been possible.

## 4.6.3 Discussion

One of the stated goals of this study was to ascertain at the experimental level the physicochemical properties of peptides derived from the proteolytic cleavage of membrane proteins, to determine if some of them belong to transmembrane helices, and to compare their characteristics with the predicted tryptic transmembrane peptides of the same identified proteins. The parameters that were chosen to characterize these peptides comprised the GRAVY score and the peptide length. The majority of the identified peptides were of medium

character (GRAVY scores between -0.5 and 0.5) and their lengths ranged from 10 to 20 amino acids. In contrast, the majority of the predicted tryptic transmembrane peptides (containing up to one misscleavage since the search criteria for protein identification permitted it) were of 20-30 amino acids length and the GRAVY values ranged from 0.5 to 1.5. Surprisingly, no transmembrane tryptic peptide was experimentally identified although, according to the GRAVY score and peptide length predictions, there was a high degree of likelihood that at least a few of those peptides should have been experimentally detected. Overall, only one tryptic peptide could be identified whose amino acid sequence encompassed half of a transmembrane helix due to the presence of a lysine in the middle of the alpha helix segment.

In this initial study, which was performed using a LTQ mass spectrometer, only peptides with assumed charge state of +1, +2 or +3 were selected for MS/MS analysis and peptide identification. As a consequence, peptides of mass above 4500 Da were not considered, excluding most of the potential transmembrane tryptic peptides. In subsequent analyses, peptide identification was performed using the newest generation mass spectrometer (the LTQ Orbitrap mass spectrometer) at 30,000 mass resolution and 2 ppm mass accuracy so that peptides with higher charge state could potentially be considered. Indeed, when the same samples were analyzed using the Orbitrap mass spectrometer, signals with charge state +4 and +5 were detected in the m/z range between 1000–1500 Da corresponding roughly to the mass of potential transmembrane tryptic peptides. However, due to software limitations and poor MS/MS spectral quality for highly charged precursor ions in the LTQ mass analyzer, these types of peptides were routinely excluded from the analysis in this first round of protein identification. Nevertheless, the exact nature of these high molecular mass, multiply charged peptides should be investigated in future studies.

There are many other reasons that may lead to the absence of transmembrane tryptic peptides. Assuming that trypsin cleaves off transmembrane helices, that is, the transmembrane tryptic peptide is generated during the digestion procedure, the rather hydrophobic nature of most of these peptides may hinder their extraction from the gel band or they may stick to tube walls during peptide extraction. Finally, very long and/or hydrophobic peptides typically cannot be chromatographically analyzed on a C18 column and might require a different stationary phase, such as Hydrophilic-Interaction Liquid Chromatography (HILIC) (see appendix C for a detailed discussion).

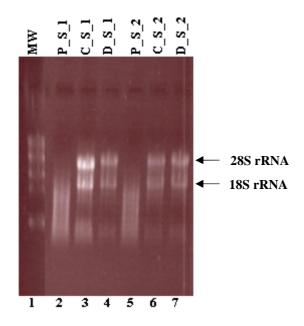

The name Hydrophilic-Interaction Chromatography (HILIC) was originally coined by Alpert (120) for the separation of hydrophilic substances such as proteins, peptides and nucleic acids polar stationary such polyhydroxyethyl aspartamide using phase. as or polyhydroxysulfotamide aspartamide. Polar peptides are retained by the polar stationary phase in a hydrophobic solvent. The solute molecule is then eluted from the chromatographic beads by increasing the polarity of the mobile phase, for example by increasing the proportion of water or by adding salt. So far, HILIC has been suggested as an alternative to cation-exchange chromatography for the separation of polar peptides, such as glycopeptides, phosphopeptides and modified histone peptides (121). It is then typically coupled off-line with a RPLC-MS for peptide characterization.

In contrast to other studies, we suggest the use of HILIC for the chromatographic separation of very hydrophobic peptides, such as typically found in transmembrane helices of membrane proteins. Such peptides, which consist of long stretches of aliphatic and hydrophobic amino acids, might not survive the initial buffer conditions of a RPLC separation: those peptides cannot be kept soluble in aqueous solutions as they form secondary structure and precipitate before being injected into the RPLC system. In addition, their hydrophobicity might cause them to stick so strongly to the stationary phase that their elution might not be possible with conventional buffer systems. In contrast, the highly organic character of the initial buffer composition of a HILIC separation would favor the stability of those kinds of peptides while the polarity of the carbonyl backbone should ensure their retention onto the polar chromatographic medium. Similarly to RPLC, HILIC can be directly coupled to an electrospray ionization interface if the salt concentration is kept to a minimum to avoid interference with the ionization process. In this configuration, HILIC-MS might provide complementary information to the conventional RPLC-MS peptide analysis.

# 4.7 Preparation of intact RNA from the Small Intestine

# 4.7.1 Monitoring RNA degradation

RNA extraction from the small intestine was prepared in sections as follows. The dissected small intestine was divided in three equal segments, which were named according to their location to the stomach. The proximal segment contained the duodenum and the proximal part of jejunum while the central segment included the central part of the jejunum. The distal segment contained the distal part of the duodenum and the ileum. This division did not follow accurately the physiological partition of the small intestine. However, it represented a good compromise for dividing quickly and reproducibly the small intestine into three representative parts while preserving most of the section specificity. Each section was then further divided into three parts to accommodate the amount of tissue in the Lysing Fast RNA Matrix D tubes. Homogenization was performed using a FastPrep Cell disrupter. Total RNA was extracted according to the protocol listed in paragraph 3.2.8, after which the RNA common to the same section was pooled. RNA quality was then assessed using a 1% agarose denaturating gel (Fig. 4.44).

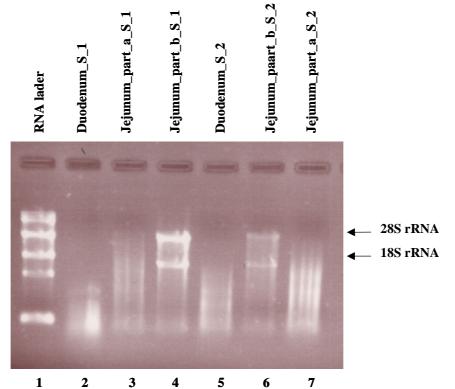

**Fig.4.44:** Total RNA analysis by denaturating agarose gel electrophoresis. Approximately 1  $\mu$ g total RNA extracted from the proximal, central, or distal sections of intestinal tissue were analyzed using a 1% agarose denaturating gel. The two intense bands highlighted by the arrows represent the heavy and the light subunit of ribosomal RNA. Lane 1, molecular weight marker (MW); Lanes 2-4 and 5-7: total RNA of the three sections from two different mice. P S, proximal section; C S, central section; D S, distal section.

Figure 4.44 shows that the 28S rRNA and 18S RNA was degraded in the proximal section of both mice while RNA quality was satisfactory for the central and distal sections. The RNA

extraction procedure was repeated on 5 additional intestinal samples to confirm that the extracted RNA was consistently degraded in the proximal sections (data not shown).

This observation led to the hypothesis that high RNAse activity might be the cause for RNA degradation in the jejunum. These RNAses might be of a different enzymatic family than in the other segments of the intestine or their specific activity could be higher in the duodenum. In order to confirm this hypothesis, the proximal part of the intestine was cut in three segments, with the most proximal part containing the duodenum while the other two segments only containing parts of the jejunum. RNA was extracted from these sub-sections and the quality of the extracted RNA was assessed again by denaturating agarose gel electrophoresis (Fig. 4.45). RNA quality was found to significantly worsen as the tissue was excised closer to the stomach. RNA extracted from the duodenum was completely degraded, while the RNA extracted from the jejunum proximal and central sections was partially degraded (jejunum proximal) or even mostly intact (jejunum central). These results confirm our hypothesis that RNAse activity is very high in the duodenum in comparison to the other sections and requires specific handling in order to isolate intact RNA for subsequent analysis.

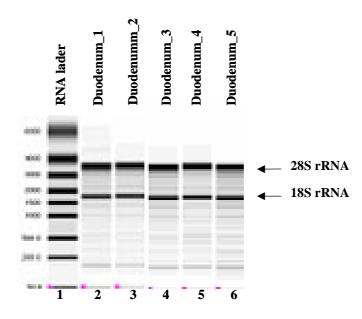

**Fig.4.45:** Total RNA analysis by denaturating agarose gel electrophoresis. Approximately 1 µg total RNA extracted from the three parts of the proximal section (duodenum, jejunum a, and jejunum b) were analyzed using a 1% agarose denaturating gel. The two intense bands highlighted by the arrows represent the heavy and the light subunit of ribosomal RNA. Lane 1, molecular weight marker (RNA ladder); Lanes 2-4 and 5-7: total RNA from the three parts of the proximal section of two different mice S 1 and S 2.

#### 4.7.2 Inhibition of RNA degradation

The analysis of gene expression along the small intestine of a mouse, in particular with the goal to compare gene expression of differentially treated mice or of mice with different genetic background, requires a much more complete inhibition of RNA degradation in the duodenum section than previously achieved.

Attempts to improve the quality of the extracted RNA by adding RNAse inhibitors in the PBS buffer used to flush the intestine or by flushing and storing the sections in RNAlater directly did not significantly prevent RNA degradation in the duodenum. Similarly, shorter homogenization steps or setting the FastPrep Cell disrupter to lower homogenization speed did not result in any significant improvement of the RNA quality. Much better results were obtained using an alternate homogenization protocol involving tissue grinding under liquid nitrogen, pointing out to a temperature increase in the tissue during the homogenization step as being one of the major causes for RNA degradation. The main advantage of the grinding procedure consists in keeping the tissue constantly frozen until it is completely embedded in the phenol- and guanidine thiocyanate-containing TriReagent, which is an effective RNAse inhibitor. The reproducibility and the improved RNA quality using this alternate protocol were tested by processing the grinded dudenum from five different mice. The resulting RNA was assessed electrophoretically using the Experion System (Bio-Rad) as shown in Fig. 4.46. The general quality of the extracted RNA from grounded duodenum sections of five different mice was significantly better. The light and the heavy subunit of the ribosomal RNA did not appear to be degraded in any of the extractions and the ratio between the 28S and 16S RNA subunits (a quality assessment for RNA degradation) was superior to 1.5 in all the samples. These results demonstrate that significant RNA degradation in the jejunum section can be avoided provided that the samples temperature is controlled during the homogenization step.

**Fig.4.46:** Total RNA analysis using the automated electrophoresis Experion System (Bio-Rad). Approximately 1 µg total RNA was loaded onto the system. The two intense bands highlighted by the arrows represent the heavy and the light subunit of ribosomal RNA. Lane 1, Molecular mass marker (RNA ladder); Lanes 2-6 extracted RNA of the dudenum section from five different mice prepared with the grinding process.

## 4.7.3 Discussion

A reliable protocol to extract good quality RNA is the first and most important factor for a successful differential analysis of gene expression. The small intestine, and in particular the duodenum, contains many peptidases and nucleases whose natural role is to degrade macromolecules such as proteins, RNA and DNA, to their constituents to facilitate their absorption through the small intestine. Their abundance and their intrinsic activity make RNA extraction of the small intestine quite challenging. A standard RNA extraction protocol based on tissue homogenization with Lysing Fast RNA Matrix D tubes in a solution that contained phenol and guanidine thiocyanate could not be used for RNA extraction of the jejunum as the endogeneous, highly active RNAses could not be inhibited sufficiently rapidly to prevent significant RNA degradation. In this study I developed a protocol for the extraction of high quality RNA enabling in future studies a comparison of gene expression between differentially treated mice. First attempts to modify the original protocol, such as speeding intestinal tissue collection and snap freezing in liquid nitrogen, flushing the collected tissue with PBS containing RNAse inhibitors, or flushing and storing the tissue in RNA later, as well as varying the homogenization process (shorter disruption time, slower disruption rate, increased cooling periods) failed to deliver a better RNA quality. A major breakthrough was obtained by replacing the homogenization step with a protocol including tissue grinding in liquid nitrogen. This alternate procedure gave optimal results for the RNA extraction from the duodenum section. The current protocol, combining a speedy tissue collection, a quick wash with PBS, snap-freezing and tissue grinding in liquid nitrogen leads to the extraction of very good quality RNA that can be stored at -80 °C for further use by gene chip analysis or qRT-PCR.

# **5. CONCLUSIONS**

The study of membrane proteins is a difficult topic on its own because of the particular characteristics of these proteins. The study of membrane proteins in a complex mixture where degradation is a natural process is even more challenging.

In this study I successfully developed a robust protocol for the BBM preparation from mouse intestinal mucosa, a tissue whose main function is to degrade nutrients in order to facilitate their ingestion. The inherent protein and RNA degradation which I faced during my early work had to be considered and taken care of to obtain a reproducible BBM preparation. A significant amount of time and effort was spent on developing protocols for the inhibition of protein and RNA degradation, which at the end was partially achieved. It is worth pointing out that none of the published studies previously dealing with BBM analysis using mass spectrometry, immunoassays or microarrays had mentioned any issue regarding tissue degradation.

A triplicate identification of the proteins part of the BBM resulted in the identification of more than 1460 proteins, of which "only" 260 were integral membrane protein, an apparently disappointing result considered that the preparation was thought to be highly enriched in membrane proteins. However, a detailed analysis of the proteins identified in the BBM preparation made apparent that a large extent of the remainder was accounted for membrane-associated, membrane-anchored proteins and cytoskeleton proteins involved in protein trafficking between cytosol and plasma membrane, thus closely related functionally to the BBM function. Even some of the 330 cytosolic proteins, such as the apolipropteins which could have been discounted as contaminant at a first glance, were demonstrated to be specifically co-enriched in the BBM fraction probably due to their interaction with a BBM-specific component.

A rough estimation of protein abundance based on peptide counts confirmed that membrane proteins and membrane-associated proteins represented the dominant species in the BBM preparation. In this analysis we didn't observe any particular bias against proteins with many transmembrane helices. Nevertheless, the identification of these proteins was based on tryptic peptides exclusively located in the loops, in extracellular areas or in the intracellular domains of the proteins. I believe that the reason for the lack of identification of tryptic transmembrane peptides (assuming that trypsin was equally active in this environment) was due in many cases to the length of the generated peptides, typically of 40-50 amino acids long. Indeed, the elution of highly charges peptides of 5-6 kDa mass were occasionally observed in the elution

chromatograms. Unfortunately, due to software limitation (peptide with charge state above +3 could not be considered in an automatic data analysis), these peptides were not analyzed and further studies will be required to confirm this observation.

This study is the first proteomic approach in which numerous receptors and transporters and many relevant proteins to cholesterol absorption were identified. This is in contrast to several recently published proteomic studies (2, 122) claiming the characterization of specific membrane proteins of BBM. However, their protein lists were mostly restricted to Ras-related proteins and cytosolic or membrane associated-proteins. Aminopeptidase N and Sodium/Glucose co-transporter, two of the most abundant proteins in the BBM, were characterized in a proteomic approach for the first time in this study. Similarly, some proteomic studies have been based on the isolation of the lipid rafts (possible BBM micro domains responsible for cholesterol absorption) to enrich and identify proteins that participate in cholesterol absorption (3). None of these studies reports the identification the Niemann-Pick C1-like protein 1, the target of ezetimibe (a cholesterol absorption inhibitor) and for many researchers the likely transporter of cholesterol. In this study, the Niemann-Pick C1-like protein 1 was one of the most abundant proteins in the purified BBM fraction.

These data re-emphasize the critical importance of a reproducible isolation and fractionation of a membrane preparation in a high-throughput proteomic approach, even if using a mass spectrometer with high resolving power and excellent mass accuracy. In this study, a robust BBM isolation protocol (in which the unspecific proteolytic activity of the preparation was controlled by adding a cocktail of protease inhibitors and peptide substrates) led us to the characterization at the protein level of a large number of cholesterol- or fat absorption-related proteins which, until now, had only been characterized at the gene level or by immunoassays. Thus, a membrane proteomic approach is feasible and may yield excellent results when the analyzed membrane fraction is optimally purified. Evidently, the requirement for a complex purification and fractionation scheme is accompanied by an increasing analysis complexity. Preparation of the BBM in sections enabled the identification of some additional BBMspecific proteins and provided some examples of protein localization along the small intestine. For example, the SR-BI receptor was identified in the BBM fraction prepared from total mucosa with one single peptide (and hence was not included in the final list in appendix A1). In contrast, it was robustly characterized in the BBM fraction prepared from the duodenum segment of the small intestine with three different peptides. The benefit of the additional fractionation was obvious in respect to the confident identification of this receptor. However, it required three times more measurement time and a rather large increase of starting material. The cost/benefit of the selected isolation scheme needs to be carefully considered in respect to how many biological replicates or differential experiments are planned.

The specific identification of the ApoE protein in the BBM fraction captured our interest and led us to a prototype comparison study between BBM preparations from ApoE knockout mice and wild type mice of the same genetic background. Following the same preparation protocol and a well established analytical strategy, we were able to see clear differences in the expression level of several proteins between the two different species. Since no quantification technique was applied and there was no biological replicate, we focused our interest in the "black and white" differences. Among them, the Ileal Bile Acid Transporter (IBAT) protein and the ApoAI protein, which were robustly identified in the wild type animals, couldn't be detected in the ApoE knockout mice. This finding was not described in any of the earlier published studies that have attempted to elucidate the reasons why the ApoE knockout mice appear hypercholesterolemic, have high plasma cholesterol and high cholesterol absorption. In particular, the striking downregulation of the IBAT transporter in the ApoE knockout animal strongly suggests a disruption of the bile acids metabolism. This hypothesis is supported by a separate study that showed that the bile acid pool size in the liver and the intestine of the ApoE knockout mice was significantly increased compare to the wild type mice. The increase of the bile acids pool available in the small intestine of the ApoE knockout mice might explain the higher cholesterol absorption of these animals since cholesterol is better solubilized and, consequently, transported more easily through the BBM. This part of my study provides a completely new perspective to the high cholesterol absorption of these animals and opens a new field of research in this topic.

Similarly to this prototype study, I am convinced that the analytical strategy described in this study is sufficiently mature to perform comprehensive comparative analysis of mice that have for example been treated with specific compound or that have been subjected to different diets. The simplistic analysis method used in the ApoE knockout example was sufficient to pinpoint to obvious changes. However, in a more complex dataset, a proper quantification strategy should provide a better leverage to discover differences with statistical significance. The <sup>15</sup>N full metabolic labeling of mice might represent an ideal strategy for this type of samples. The mixing of an internal standard in the form of a "heavy" BBM preparation in all the samples of interest enables very accurate protein quantification (in principle, all BBM proteins could be normalized to their specific internal standard) over the whole experiment. In addition, the co-purification of the <sup>15</sup>N internal standard with the regular BBM preparation provides a mean to compensate for variability in degradation across the experiment.

A significant amount of time and effort was spent in this study for evaluating the stability of the BBM preparation protocol, the reproducibility of the analytical steps leading to the protein identification and, further, the consistence of these analyses with an initial comparative investigation of how to extract the same information directly from the LC-MS precursor ion signals. Overall, the BBM isolation protocol that was developed in this study, combined with a reproducible analytical strategy, enabled us to identify almost 90% of all the 1639 proteins identified in the BBM fraction in at least two of three triplicates. This level of reproducibility was beyond our expectations and encouraged us to individually monitor the variability of each of the technical steps involved in the procedure. The data confirmed the critical stability and reproducibility of the Orbitrap mass spectrometer for the high throughput analysis of such samples. The study pinpointed to an unexpected source of variation in the form of the LC buffers, which need to be tightly controlled to obtain reproducible chromatographic separation conditions. Ideally, samples to be compared must be analyzed using identical buffer and column batches on the LC system.

My study in this respect initiated a discussion for better understanding the analytical requirements and the type of software tools that might allow in the future label-free quantification approaches based on LC-MS data alone. Quantification at the precursor mass signal intensity might provide a more general method of comparison for LC-MS-based proteomics studies than the comparison of protein lists, which only consider approximately 10 to 20% of the available data. Protein identification of signals of interest can then be obtained using MS/MS inclusion lists, where an ion signal of specific m/z and RT is targeted for tandem mass spectrometric analysis. Most importantly, the ability to differentially compare samples across an experiment first requires the knowledge of what is common to the technical and biological replicates of samples so that the significance of a given change can be statistically appreciated. Within this study, we determined what was achievable with regards to reproducibility using standard protein purification technique and advanced analytical strategies but we also described the current limitations that will need to be addressed in the future to fully enable this strategy.

# 7. ABBREVIATION

ABC	Ammonium Bicarbonate
ACN	Acetonitrile
a-CYANO	a-Cyano-4-hydroxy-cynnamic-acid
AF	Ammonium Formate
BBM	Brush Border Membrane
Bicine	N,N-Bis(2-hydroxyethyl) Glycine
<b>Bis-Tris</b>	Bis(2-hydroxyethyl)amino-tris(hydroxymethyl)methane
BSA	Bovin Seum Albumin
βΜΕ	beta Mercaptoethanol
DTT	1.4 Dithioerythritol
EDTA	Ethylenediaminetetraacetic acid
ESI	Electrospray ionization
EtBr	Ethidium Bromide
FA	Formic Acid
GC	Gas Chromatography
GRAVY	Grand average of hydropathicity
HILIC	Hydrophilic Interaction Chromatography
IAA	Iodoacetamide
КО	Knockout
LC	Liquid Chromatography
LDS	Lithium dodecyl sulfate
MALDI	Matrix-assisted laser desorption/ionization
MOPS	3-(N-morpholino) ethane sulfonic acid
PMSF	Phenylmethylsulfonylfluorid
PVDF	Polyvinylidene difluoride
RPLC	Reverse Phase chromatography
RT	Retention time
SDS	Sodium dodecyl sulfate
TBS	Tris Buffer Saline
TFA	Trifluoroacetic acid
THF	Tetrahydrofuran
TOF	Time of flight
TTBS	Tween Tris Buffer Saline
WT	Wild type

# 8. ACKNOWLEDGEMENTS

I am especially grateful to my two supervisors Prof. Dr. Michael Karas, from Johann Wolfgang Goethe-University of Frankfurt, and PD Dr. Hanno Langen, from F. Hoffmann-La Roche Ltd in Basel, who were great source of inspiration to me. I would like to thank them for accompanying this PhD project with their scientific interest and guidance, for their generous support as well as for helpful discussions and encouragement.

I am grateful to Prof. Dr. Klaus Lindpaintner, Head of the Roche Centre of Medical Genomics (RCMG) at that time, for offering me the opportunity to carry out my PhD work in the Proteomics group and for sponsoring my thesis. During all these years working in this group, I have not only expended my scientific knowledge and strengthened my knowledge in the field of proteomics but I also have had the privilege to be exposed to the research environment in the pharmaceutical industry, an invaluable experience that will contribute in shaping my professional career.

I am indebted to Dr. Axel Ducret, directing the mass spectrometry team at the RCMG at that time, who was a great mass spectrometry teacher for all these years. Our numerous and constructive discussions, his continuous support, his helpful tips about planning and conducting high-throughput proteomics studies, and his patience in reviewing my manuscripts helped me to make my PhD thesis a reality.

I am thankful to Dr. Eric Niesor, head of the Metabolic Disease department at Roche at that time, and the members of his team: Dr. Margrit Schwartz, Dr. Evelyne Chaput, Dr. Martin Benson, Dr. Roger Clerc, Denise Blum and Christophe Gardes for the many helpful discussions on the biology around the small intestine. Roger and Christophe supported me in developing a protocol for RNA extraction based on the needs of my project. Margrit guided my first steps in the Brush Border Membrane biology and Evelyne helped me to better understand the science around cholesterol absorption. On the basis of my results, she conducted a study to measure the bile acid pool size in liver and the small intestine of ApoE knockout mice. Her results confirmed the findings of my study and opened a new area for hypothesis generation and discussions between the two teams.

I am obliged to Dr. Nikos Berntenis and his Bioinformatics team members at the RCMG, Dr. Jens Lamerz and Dr. Franz Roos, for their patience and their support in providing me with the bioinformatics tools for the analysis of my data. In particular, Nikos estimated the false discovery rate at the peptide level for the correlation of tandem mass spectra with sequence databases and he spent a significant amount of time introducing me to the structure of MSpresso, the in-house database that he developed to consolidate and facilitate the interpretation of MS/MS data generated by tandem mass spectrometers. Jens and Franz

supported me in the design of a study to monitor the stability and the variability along the BBM preparation and their LC-MS analyses. I am especially grateful to Franz for his contribution in comparing LC-MS data and in finding a way to express sample similarity. Throughout my PhD thesis, Jens, Franz, Nikos, Axel and I had many constructive and fruitful discussions around comparison of LC-MS signals which led us to better understand the analytical requirements and the software tools that might allow in the future performing label-free quantification experiments based on LC-MS data only.

I am grateful to Dr Martin Ebeling, of the Bioinformatic group of Pharma Research at Roche, for his contribution on deriving the topology and the membrane prediction of the BBM proteins characterized in this study.

I am also thankful to Dr. Peter Berndt for our constructive discussions around membrane proteomics and protein degradation. I really appreciated that he was always available whenever I needed his support.

I am also grateful to my former colleagues of the mass spectrometry group, Dr. Hans-Werner Lahm, Sabine Kux van Geijtenbeek, Daniel Röder, Christian Miess and Arno Friedlein, and Dr. Andreas Tebbe and Dr. Elsa Wagner for their help, their friendship, and the nice working atmosphere in the laboratory. I am especially thankful to Sabine and Elsa for our discussions, their encouragement in difficult moments, and for some distraction with coffee and sweets.

I would also like to thank all the RCMG members for being there and trying to help whenever I needed them.

I am also thankful to my current colleagues and especially my line manager, Lesley van Jaarsveldt, for their friendship, their support, and for giving me the time to finish writing my thesis.

Finally, I would like to extend my warmest thank you to my parents, my brother, and my friends for sharing my worries and for encouraging me to continue whenever I thought that I would give up.

Last, but not least, the biggest thank you to the ones who matter most:

- My daughter Nephelie for putting up with a hardworking mother and for reminding me of what is valuable in life. Thank you for being my little girl.
- My partner Axel for his love and his support. I wouldn't have been able to do all this without you. Thank you for being who you are!

## APPENDIX

## Appendix A. Protein identification

### A1. BBM protein identification from whole mucosa

Total list of the 1306 identified BBM proteins from whole mucosa with a valid Swissprot database entries, listed by topology, then alphabetically according to their gene symbol. The color coding is as follows: yellow, "membrane" protein as predicted by the ALOM tool; blue, "secreted" protein as predicted by the "signal\_anchor" software tool; green, "non-membrane, non-secreted" (=cytosolic) protein; red, proteins not analyzed by those software packages and manually added to the table.

- Gene ID: internal Roche gene ID number
- Gene Symbol, Swissprot protein ID, Swissprot protein AC: associated gene symbol, protein ID and protein accession number in the Swissprot database.
- Gene Description: description of gene product as provided by the internal Roche database entry
- Max Diff peptide: maximum number of different peptides observed in anyone of the triplicate LC-MS/MS analysis
- **Avg Pep count**: sum of peptide counts for all the LC-MS analysis of this protein divided by the number of LC-MS analysis it has been detected.
- **Rank order:** protein abundance ranking based on average peptide counts in the tripliocate LC-MS analysis.
- Ortho Gene Symbol, Ortho Swissprot protein ID, Ortho Swissprot protein AC: associated orthologous (human) gene symbol, protein ID and protein accession number in the Swissprot database, as provided by the Roche internal database.
- **Topology:** predicted protein topology: c=cytosolic, tm=transmembrane, s, secreted. Proteins labelled "ad" were manually added to the table after the topology analysis was performed.
- GO term: GO annotation for the protein cellular location
- Protein length: length of protein in amino acids
- **Number of TM:** predicted number of transmembrane domains according to the TMHMM software package.

## A2. BBM protein identification from small intestine sections

Total list of the 1625 identified BBM proteins from sections or from whole mucosa. The protein must have at least a diff. peptide count of two in any of the 4 analysis to be included in the table. The proteins are listed by decreasing maximum number of different peptides.

Gene Symbol: associated gene symbol

- Gene Description: description of gene product as provided by the internal Roche database entry
- **Sum of Sum\_Pep\_count Pep count**: sum of peptide counts for all the LC-MS analysis of a given protein for a section or the whole mucosa analysis.
- Max of Max\_Diff\_peptide: maximum number of different peptides observed in any of the LC-MS analysis from a given section or whole mucosa analysis
- Proximal, central, distal: small intestine sections in contrast to whole mucosa

# Appendix C: Separation of hydrophobic peptides by hydrophilicinteraction liquid chromatography

### **C.1 Introduction**

Reversed-Phase Liquid Chromatography (RPLC) has become an indispensable technique for the separation and purification of peptides using hydrophobic stationary phases, such as octyl- or octadecyl-derivatized silica beads. In RPLC, a solute molecule binds to an immobilized hydrophobic molecule in a polar solvent. This partitioning occurs as a result of the solute molecule tending to have hydrophobic patches at its surface and binding occuring via those patches to the matrix. A buffer of increasing hydrophobicity is used to dissociate the bound molecule at a point at which the hydrophobic interaction between the exposed patches and the immobilized matrix is less favorable than the interaction between the bound molecule and the solvent. The molecule releases from the matrix and elutes. One of the major advantages of the RPLC technique, apart from its extensive resolving power, is the availability of volatile mobile phases, of which aqueous trifluoroacetic acid (TFA), acetic acid or formic acid–acetonitrile (ACN) are the most frequently employed (123). Thus, RPLC can be directly coupled to an electrospray ionization interface for the online analysis of molecules using mass spectrometry.

Although a powerful separation mode, a major limitation of RPLC is the lack of adequate retention of polar molecules. In 1990, the name Hydrophilic-Interaction Chromatography (HILIC) was coined by Alpert (120) for the separation of hydrophilic substances such as proteins, peptides and nucleic acids using polar stationary phase, such as polyhydroxyethyl aspartamide or polyhydroxysulfotamide aspartamide. In HILIC, polar peptides are retained by the polar stationary phase in a hydrophobic solvent. The solute molecule is then eluted from the chromatographic beads by increasing the polarity of the mobile phase, for example by increasing the proportion of water or by adding salt. Similarly to normal phase liquid chromatography (or in opposite to the trends observed in RPLC) peptide retention time increases with the polarity (hydrophilicity) of the peptide and critically depends on the polarity of the stationary phase and on the initial polarity of the mobile phase (124-126). It has been considered that the interaction forces governing selectivity in HILIC are polar in origin, encompassing both hydrogen bonding, the extent of which depends upon the acidity or basicity (in the Lewis sense) of the solutes, and dipole-dipole interaction, which is dependent upon the dipole moments and polarizability of molecules (124). Similarly to RPLC, HILIC can be directly coupled to an electrospray ionization interface if the salt concentration

is kept to a minimum to avoid interference with the ionization process. However, so far, HILIC has been suggested as an alternative to cation-exchange chromatography for the separation of polar peptides, such as glycopeptides, phosphopeptides and modified histone peptides (121). It is then typically coupled off-line with a RPLC-MS for peptide characterization.

In contrast to most studies, where HILIC has been used to chromatography very polar peptides, the main point of interest in this work was to investigate the potential of HILIC to cope with the separation of very hydrophobic peptides, such as typically found in transmembrane helices of membrane proteins. Such peptides, which consist of long stretches of aliphatic and hydrophobic amino acids, and which might count an average of 40-50 amino acids in a tryptic digest, are typically not observed in a classical RPLC-MS separation. One likely explanation is that they might not survive the initial buffer conditions of a RPLC separation: those peptides cannot be kept soluble in aqueous solutions as they form secondary structure and precipitate before being injected into the RPLC system. In addition, their hydrophobicity might cause them to stick so strongly to the stationary phase that their elution might not be possible with conventional buffer systems. In contrast, the highly organic character of the initial buffer composition of a HILIC separation would favor the stability of those kinds of peptides while the polarity of the carbonyl backbone should ensure their retention onto the polar chromatographic medium.

The purpose of this work was to compare side-by-side the behavior of commercially available RPLC and HILIC chromatographic media in the separation of peptides of various hydrophobicities and to derive a first impression whether the premises delineated above could be verified.

## **C.2 Materials and Methods**

### C.2.1 Peptide synthesis

Selected peptides from bacteriorhodopsin were synthesized using standard peptide synthesis chemistry. Peptides 1-3 were synthesized at Peptide Specialty Laboratory (Heidelberg, Germany) while peptides 1-43 and 129 were synthesized at the peptide synthesis group at Roche Penzberg.

Peptide	Peptide sequence	Number of AA	Theoretical Mass (m/z)	GRAVY
	MLELLPTAVEGVSQAQITGRPE			
Peptide 1-43	WIWLALGTALMGLGTLYFLVK	43	4686.5445	0.74
	FVWWAISTAAMLYILYVLFFGF			
Peptide 129	TSK	25	2974.562	1.424
Peptide 1	VGFGLILLR	9	987.6354	1.956
Peptide 2	AESMRPEVASTFK	13	1452.7156	-0.523
Peptide 3	AIFGEAEAPEPSAGDGAAATSD	22	2032.886	-0.195

**Table A.I:** List of synthetic tryptic and C-terminal (peptide3) peptides from bacteriorhodopsin. The GRAVY score (grand average of hydropathicity, see Kyte, J. and Doolittle, R.F. (1982) A simple method for displaying the hydropathic character of a protein. J. Mol. Biol. 157, 105-132) was calculated using the ProtParam tool on the Expasy web site (www.expasy.ch). A positive GRAVY score indicates an hydrophobic sequence while a negative GRAVY score points to hydrophilic sequence. The theoretical mass of the peptide was calculated for a charge state of 1+.

## C.2.2 Capillary RPLC

Peptide mixtures were analyzed by capillary reverse phase liquid chromatography using an Agilent 1100 microflow chromatographic system using a 0.3 mm i.d x 15 cm length C18 PepMap100 (3 µm particle, 100 Å pore size, Dionex) column.

The peptide mixture of each sample was dissolved in buffer A (5% ACN, 0.1% FA). 20  $\mu$ l of the sample was transferred to a glass Micro-V vial (Agilent) of which 10  $\mu$ l were injected into the system at a flow rate of 5  $\mu$ l/min at 5% buffer B (90% ACN, 0.5% FA) for 9 min. The peptides were eluted from the reverse phase column by increasing the ACN concentration in a linear gradient as follows: 9–48 min, 5–60% buffer B. The column was then washed for 10 min with 90% buffer B after which it was re-equilibrated for 28 min in 5% buffer B.

#### **C.2.3 Capillary HILIC**

Peptide mixtures were analyzed by HILIC chromatography with the same Agilent 1100 HPLC system that was used for the capillary RPLC method using a 0.3  $\mu$ m i.d. x 15 cm length PolyHYDROXYETHYL-A (5  $\mu$ m particle, 300 Å pore size, PolyLC Inc) column.

The peptide mixture of each sample was dissolved in buffer A (90% ACN, 0.1% FA, 5 mM ammonium formate). In some cases samples were dissolved in buffer A with the addition of either 0.05% SDS, 0.05% Triton X-100 or 10% tetrahydrofurane. 20  $\mu$ l of the sample was transferred to a glass Micro-V vial (Agilent) of which 10  $\mu$ l were injected into the system at a flow rate of 5  $\mu$ l/min at 100% buffer A for 9 min. The peptides were eluted from the HILIC column by decreasing the ACN concentration in a linear gradient as follows: 9–48 min, 0–61% buffer B (5 mM ammonium formate, 0.1% FA). The column was then washed for 10 min with 88.5% buffer B after which it was re-equilibrated for 28 min in 100 % buffer B.

#### C.2.4 MALDI MS analysis, data processing and analysis

Peptides eluted between 10 and 70 min retention time were directly spotted onto the 384 positions of an Anchorchip target plate (Bruker Daltonics) pre-coated with matrix. Shortly, each position of the 384 anchorchip target plate was pre-spoted with 1  $\mu$ l of  $\alpha$ -cyano-4-hydroxycinnamic acid (0.25 mg/ml in 0.2 %TFA, 65 % Ethanol and 32% ACN containing 20 fmol/ $\mu$ l ACTH and bradykinin as peptide standards). After spotting, spots were re-crystallized at 4 °C using 1  $\mu$ l of 65% Ethanol, 32% ACN. Peptides were analyzed in a LC-MALDI modus with an Ultraflex I MALDI mass spectrometer (Bruker Daltonics) in reflector mode using standard operating procedures.

The LC-MALDI raw data of each fraction-spot were processed and filtered using an in-house software (MEDUSA). The algorithm (developed in the Proteomics group by Peter Berndt) removes most of the chemical noise introduced by the MALDI process and group related MS signal to a single variable (a chain). All spectral features (i.e., a peptide mass spectrometric signal) detected over a minimal signal over noise were extracted and internally calibrated. All those masses obeying a chromatographic behavior (i.e., the mass of an eluting peptide is expected to be observed in several consecutive fractions) were then clustered together using a star-shaped tolerance region and a nearest neighbor connected graph is build. For each connected component of the graph, the weighted mass and rf average and its error is estimated The algorithm removes most of the chemical noise, i.e. chemical components that are either continuously observed over the whole LC-MS procedure or that are randomly measured in

one or the other fraction, while keeping real features. The filtered signals were then graphically displayed using the Spotfire software package (TIBCO).

Protein identification from LC-MALDI analyses was performed as follows: The compiled peptide m/z masses obtained from the MEDUSA software package were analyzed using the MASCOT search algorithm (MASCOT version 2.1.04, Matrix Science). Searches were performed against the Human SwissProt database (version 49.1 February 2006, 13488 entries) with a mass tolerance of 50 ppm .Methionines (reduced/oxidized; +15.9949 Da) were considered as differential modifications while cysteines were considered as fully carbamidomethylated (+57.0199 Da). Only fully tryptic peptides with no more than two miscleavages were considered for data analysis.

# C.3 Results

We examined in this study the chromatographic behavior of model peptides in respect to their retention time using either a RPLC or a HILIC modus. We were particularly interested in investigating the influence of peptide length and hydrophobicity onto peptide separation. We further examined the generality of both chromatographic systems by analyzing a simple protein digest by LC-MALDI MS and by identifying the population of peptides preferentially separated by a given separation modus.

#### C.3.1 Model peptides separation

A peptide mixture consisting of five synthetic peptides from bacteriorhodopsin (see Table A.1) and of ACTH was dissolved in the appropriate buffer and 10  $\mu$ l of the mixture was then injected in the Agilent 1100 LC system. The final amount of each peptide in the injected sample was 1 pmol. Samples were analyzed either freshly after dilution in the initial buffer condition or after overnight incubation at 4 °C so that the peptide stability in the sample could be monitored.

The elution profiles of the peptide mixture using either RPLC or HILIC are shown in figure C.I.

Using the RPLC modus, all peptides could be chromatographically resolved except P129 (25 AA length and Gravy score of 1.424). The peptides' retention time followed roughly their hydrophobicity reverse order, with P2 (Gravy: -0.523) eluted first followed by P3, ACTH, P1 and P1-43. The elution of the very hydrophobic P1 peptide (according to the Gravy score) prior to P1-43 shows that the length of the peptide plays an important role. In particular, it can be inferred that the C-terminal Arg might significantly affect the chromatographic behavior of this otherwise rather short peptide. Interestingly, P1-43 (43 AA length and Gravy: 0.74) was only observed in the elution profile when the sample was analyzed freshly after dilution. These data suggest that long and/or hydrophobic peptides might not remain in solution using the polar solvent system required by the RPLC chromatography. In addition, such peptides will tend to stick on the surface of the vial or will be irreversibly bound to the  $C_{18}$  column.

Using the HILIC modus, all peptides including P129 could be chromatographically resolved. As expected, the peptides' retention time followed roughly their hydrophobicity order, with P129 (Gravy: -1.424) eluted first followed by P1, P2, P1-43, P3 and ACTH. The early elution of the hydrophilic peptide P2 (according to the Gravy score) prior to P3 and P1-43 also

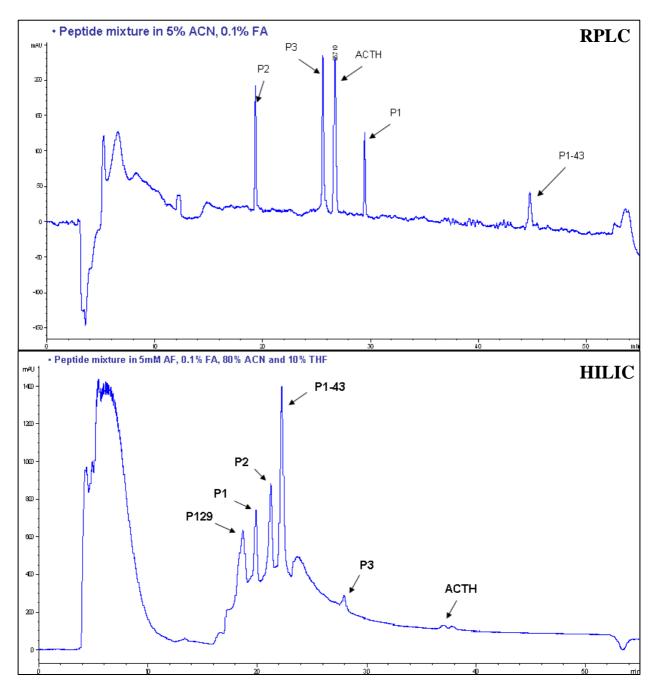

Fig.C.I: Elution profiles of the Bacteriorhodopsin peptide mix plus ACTH. Ppeptide elution was monitored online at 214 nm. RPLC: 10  $\mu$ l of the peptide mixture dissolved in 5% ACN and 0.1% FA were injected onto a C<sub>18</sub> column and eluted using an ACN linear gradient (5–56% ACN). HILIC: 10  $\mu$ l of the peptide mixture dissolved in 80% ACN, 0.1% FA, 5 mM AF and 10% THF were injected onto a HILIC PolyHYDROXYETHYL-A column. The peptides were eluted by lowering the ACN concentration in a linear gradient (90–10.35% ACN).

indicates that hydrophilic interaction might not explain all the principles behind retention and separation in HILIC. An interesting aspect of HILIC is its compatibility with the use of very hydrophobic organic solvent, such as tetrahyrofurane (THF), and with the use of detergents, such as SDS or Triton-X100. In this experiment, the peptide mixture was either dissolved in buffer A (90% ACN, 0.1 % FA, 5 mM ammonium formate), or with the addition of 0.05%

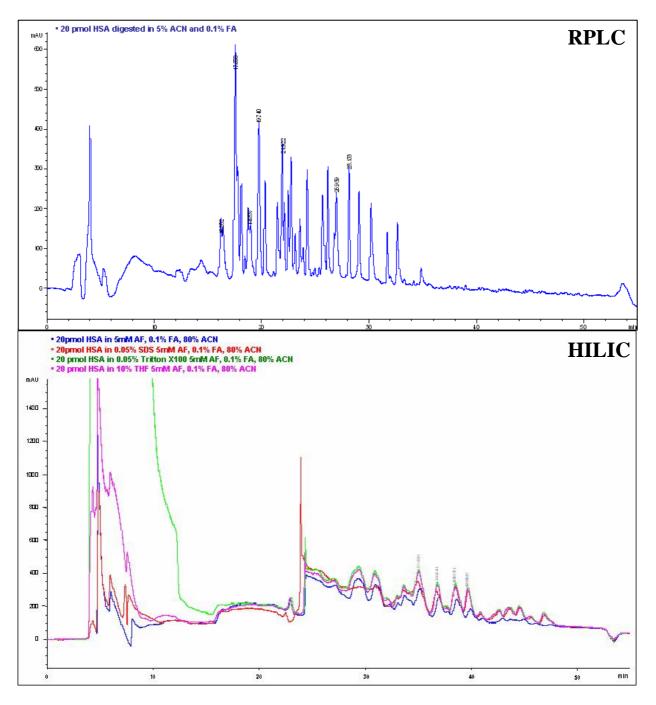

SDS, 0.05% Triton X100 or using 10% THF. The presence of those modifiers didn't affect the chromatographic behavior of the HILIC column (as they were eluted in the injection peak) and all the peptide were eluted with the same order in all the condition described above (data not shown). The addition of THF in the sample buffer was observed to slightly increase the signal intensity in the elution chromatogram. The addition of those modifiers, combined with the organic character of the sample buffer, had a beneficial effect on the peptide's stability: all peptides could be observed in the elution chromatogram even after an overnight incubation at 4  $^{\circ}$ C.

#### C.3.2 Separation of a peptide digest

In a subsequent experiment an HSA digest was analyzed using the Agilent 1100 HPLC system comparing the chromatographic separation of the  $C_{18}$  and the HILIC stationary phases. The HSA digest was prepared in the appropriate buffer and 10 µl (corresponding to 20 pmol of the digest) were injected into the system. LC fractions were collected every 9.4 sec and directly spotted onto the pre-coated 384 anchorchip target plate for subsequent MALDI MS analysis.

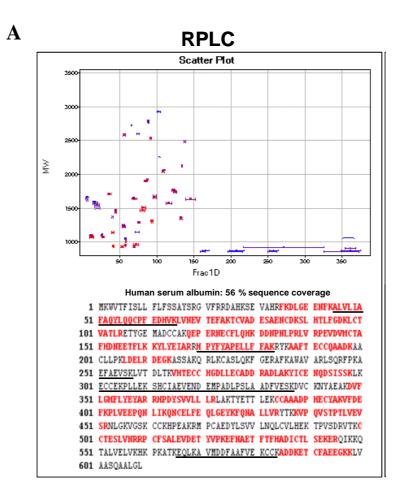

The elution profile of the 20 pmol HSA tryptic digest using either the RPLC or the HILIC chromatographic system is represented in the figure C.II.

Using the RPLC modus, the chromatographic separation of the HSA digest resulted in well resolved, sharp, intense peaks. Peak width was around 20-30 sec, ensuring maximum sensitivity for UV and MALDI MS measurement. In contrast, using the HILIC modus, the separation of the HSA digest resulted in an apparently poorly resolved elution chromatogram with peak elution time in the min range. As a consequence, typical peak only reached 100-200 mOD sensitivity at 214 nm absorption compared to 600-800 mOD reached with the RPLC modus. The presence of SDS, Triton X-100 or THF in the starting buffer did not have any noticeable effect on the chromatographic behavior of the HILIC column, except to cause a rather large injection peak. Interestingly, none of the HSA tryptic peptides eluted as early in the HILIC mode as the very hydrophobic rhodopsin peptides, indicating that the HSA digest contains mostly hydrophilic peptides. This is consistent with the elution chromatogram of the same digest in RPLC modus, where most peptides were eluted rather early in the chromatogram.

**Fig.C.II:** Elution profiles of a 20 pmol HSA digest. Peptide elution was monitored online at 214 nm. **RPLC:** 10 μl of the digest dissolved in 5% ACN and 0.1% FA were injected onto a C<sub>18</sub> column and eluted using an ACN linear gradient (5–56% ACN). **HILIC**: 10 μl of the digest were injected onto a HILIC PolyHYDROXYETHYL-A column. The peptides were eluted by lowering the ACN concentration in a linear gradient (90–10.35% ACN). **Blue**, HSA digest in 90% ACN, 0.1 % FA, 5 mM AF; **Red**, HSA digest in 90% ACN, 0.1 % FA, 5 mM AF plus 0.005 % SDS. Green, HSA digest in 90% ACN, 0.1 % FA, 5 mM AF plus 0.05 % Triton X-100; **Pink**, HSA digest in 80% ACN, 0.1 % FA, 5 mM AF plus 10 % THF.

The LC-fractions spotted onto the MALDI target were measured using an Ultraflex I MALDI mass spectrometer operated in the reflector mode. The raw data files of each fraction were filtered by the in-house MEDUSA software (Signal-to-noise ratio:12, chain length: 4) and then searched using the MASCOT search engine against the human SwissProt database at 50 ppm mass accuracy . The identified HSA tryptc peptides and their elution pattern in the RPLC or in the HILIC chromatography are schematically represented in Fig. C.III.

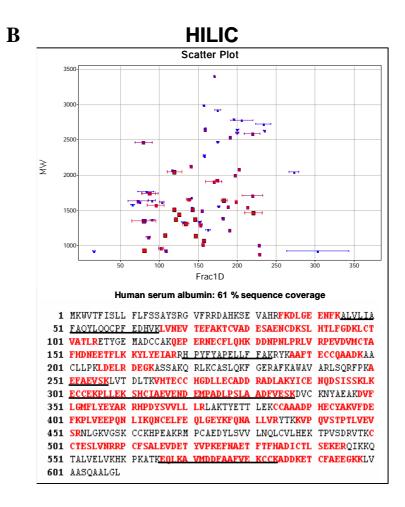

Fig. CIII: Scatter plot and sequence coverage of the 20 pmol HSA digest analyzed in the RPLC (panel A) or in the HILIC (panel B) modus. The scatter plot represents the LC-MALDI MS signals observed above the set threshold and chainlength (LoN: 12, chainlength: 4). The x axis represents the 384 fractions (the retention time) that have been collected during the RPLC run while the y axis stands for the molecular mass of the signals. The MALDI MS signal intensity is denoted by a color gradient from blue (low) to red (high). The number of fractions for which a signal has been observed is represented by the length of the horizontal line. The HSA amino acid sequence coverage for each chromatographic modi is schematically represented by highlighting the identified peptides in red. Peptides that were identified in only one of the two chromatographic separations are underlined.

The peptides that were exclusively identified in one of the two chromatographic systems are listed in the table C.II

#### **C.4 Discussion**

Reverse-phase chromatography is at present the most commonly used chromatographic separation method for the analysis of peptides and proteins by mass spectrometry. Since its first use in the late 70' (127), 30 years of intense and systematic research has resulted in the development of stationary phases and columns with excellent resolution and sensitivity, for example, for the separation of small molecules and of peptides in complex biological samples. In particular, the decreasing size of the chromatographic beads (from 8 to 5, then 3 to today 1.8  $\mu$ m diameter) enables the packing of nanoLC column (typically from 100 to 50  $\mu$ m inner diameter) with unmatched resolution and sensitivity. Their coupling to the latest generation of mass spectrometers (e.g. Orbitrap or Q-ToF) allows the characterization of peptides in complex mixtures at the attomole level.

The optimal use of RPLC in the separation and analysis of peptides by mass spectrometry requires the analyzed biological samples to be void of salt (which would significant impair the electrospray process) and to be dissolved in an almost 100% aqueous solution before separation. While most peptides (and in particular tryptic peptides) withstand such conditions without problems, long, hydrophobic peptides and some proteins might stick to vial surfaces or precipitate out of solution. In addition, the hydrophobic nature of the RPLC chromatographic material will cause very hydrophilic peptides (such as phosphopeptides) to wash through the column at injection. On the other hand, very hydrophobic peptides (such as transmembrane peptides) will tend to bind strongly to a RP stationary phase and might not be eluted from the column even at high organic content of the mobile phase. This last problem can be partially alleviated by using less hydrophobic column material, such as  $C_8$  or  $C_4$ , however at the cost of lower chromatographic resolution.

Since its description (120) in the early 90's, hydrophilic interaction liquid chromatography (HILIC) has been mainly used to chromatography and separate very polar analytes. Its mode of separation, which appears to be complementary to the RPLC chromatographic modus, has been best characterized using aspartimide-derivatized silica beads available commercially under the brand name PolyHYDROXYETHYL-A. Several studies demonstrated that mechanisms for retention and selectivity could mainly be explained by polar interactions (hydrogen bonding, dipole-dipole moments) and ion-exchange mechanisms, while the residual charges of the column's silanol groups might also provide selectivity for polar molecules (124, 128).

In this report our interest was mainly focused on the chromatographic behavior of long, hydrophobic peptides (such as generated from a tryptic digestion from membrane proteins) using HILIC. The main hypothesis behind this study relies on the observation that even long transmembrane peptides display a significant share of polar functions in the form of the carbonyl groups distributed on the peptide backbone, which should enable their retention on a HILIC stationary phase. In addition, the organic conditions typically used in HILIC and the compatibility of this chromatographic modus with various non-ionic detergents and modifiers should stabilize hydrophobic peptides better than in aqueous conditions prior to chromatographic separation. The elution profile of synthetic peptides from bacteriorhodopsin and ACTH (table A.I) using a PolyHYDROXYETHYL-A column confirmed the above idea. All the investigated peptides could be retained and separated by HILIC even if the sample was stored overnight at 4 °C to test peptide stability in those conditions. In contrast, only five of the six investigated peptides could be investigated using the C<sub>18</sub> RPLC column. Peptide p1-43 could only be analyzed if the freshly-made sample was immediately injected into the HPLC system while peptide p129 was never detected, either because it precipitated out in aqueous conditions and/or because it could not be eluted from the column. Most interestingly, HILIC is compatible with organic modifiers, such as 10% THF, or detergents, such as 0.05% Triton-X100 or 0.05% SDS, as these chemicals are eluted with the injection peak and don't appear to interfere with the chromatographic separation. These reagents also contribute to the stability and the solubility of long, hydrophobic peptides or proteins in aqueous solution. Their use might open the possibility to directly analyze by HILIC-MS intact hydrophobic proteins or to digest hydrophobic proteins in presence of detergents or hydrophobic modifiers using experimental conditions that would be otherwise incompatible with RPLC.

The separation of a HSA tryptic digest using either RPLC or HILIC essentially confirmed the observations made with the bacteriorhodopsin and ACTH peptides, with the note that the chromatographic separation and resolution of the  $C_{18}$  column was considerably higher than those of the HILIC material. The eluent of the LC columns was directly spotted onto the 384-positions MALDI target, which allowed the analysis of the peptide mixture by MALDI-ToF MS. Based on sequence coverage, both chromatographic methods roughly equaled each other (61% vs. 56% for HILIC vs. RPLC). As expected, peptides commonly analyzed in both chromatographic modi were eluted in a "complementary" order (that is, peptides eluted early in the RPLC column tended to be eluted late in the HILIC column, and vice versa). Only five peptides were found in a single chromatographic modus (table A.II) with a trend for short, hydrophilic (probably not retained in a RPLC column) and long, hydrophobic (probably not

eluted from the RPLC column) peptides preferably observed on the HILIC column. The reason for observing  $p_{45-65}$  and  $p_{170-183}$  only in RPLC modus is not clear and might be due to the inferior performance of the HILIC column. A more systematic study using protein digests of diverse origins (especially from membrane preparation, see also below) should clarify in which conditions HILIC chromatography might provide advantages compared to RPLC.

This study summarizes a first set of experiments that was performed in our group to assess the use of HILIC for the chromatographic separation of peptides, and its potential for direct coupling to mass spectrometers. The ability to analyze peptide and protein samples in presence of high content of organic solvents (that is, for an enzymatic digestion, directly after digestion without a need for evaporation and reconstitution in aqueous conditions) leads to higher sensitivity. In particular, these conditions are beneficial to keep hydrophobic, long peptides in solution. Concomitantly, a chromatography performed with organic, volatile mobile phases is ideal for efficient desolvation and peptide ionization, in effect enhancing signal response in MS and leading to higher limits of detections (129). Interestingly, we have now several lines of evidence that even highly hydrophobic peptides (such as p1-43 or p129, table A.I) are amenable to mass spectrometric detection using electrospray ionization, provided they survive the reconstitution and the chromatographic steps. These peptides typically exhibit lower charge state as their hydrophilic counterpart and might not be detected in the "typical" mass range window scanned by the mass spectrometer.

In this study, due to time constrains, only one HILIC stationary phase (polyhydroxyethyl aspartamide) could be tested among many others that are potentially available, such as silica, amino, diol, or cyano. All these phases share roughly the same mode of operation but with a large range of specificity. In particular, the amino stationary phase appears to be particularly suited for peptide separation using solvent conditions close to RPLC as it does not require salt to minimize ion-exchange interactions. However, optimal separation conditions were achieved using TFA as an organic modifier (to shield from uncapped silanol groups), compromising thereby sensitivity using an electrospray ionization interface (125). One of the major difficulty performing this study was to find columns in the sub-microbore range (<500  $\mu$ m i.d.) and/or bulk chromatographic media compatible with the packing of nanoLC column. Since the first report in 1990, HILIC has remained a niche chromatographic method for the separation of very polar compound and has lacked the development that has witnessed RPLC. However, recently, several groups have started to use HILIC for peptide separation (in particular, for the analysis of post-translational modifications, such as phosphorylation or glycosylation of peptides) and several chromatographic companies are now offering

stationary phases that could be used for the packing of nanoLC HILIC columns. A further improvement in separation could be obtained by monolithic structures instead of porous material, enabling the use of longer columns with improved peak capacity (130).

While this study provides some directions on how to analyze very hydrophobic peptides by LC-MS, the problem on how to generate such peptides and on how to keep them amenable to LC-MS analysis has not been considered here. One obvious limitation of the in-gel digest procedure remains the conditions in which the enzymatic digestion step has to be performed to avoid denaturing the proteolytic enzyme. There is at the moment no evidence that such hydrophobic peptides are generated in this procedure, and whether these peptides can be extracted efficiently from the gel matrix before they precipitate or aggregate. In the future, it will be of great importance to study the problematic in its entirety to understand whether an improved digestion protocol for membrane proteins, which should generate a better sequence coverage, in particular for transmembrane domains, can be expected at all.

# **PUBLICATIONS**

#### The work presented on this thesis will contribute to the following publications:

<u>E. Tsirogianni</u>, M. Karas, H. Langen & A. Ducret "Characterization of Brush Border membrane proteins of mice intestinal mucosa. Emphasis to the study of cholesterol absorption", *to be submitted Jan 09* 

<u>E. Tsirogianni</u>, F. Roos, Jens Lamerz, M. Karas, H. Langen & A. Ducret "Brush Border Membrane preparation and protein identification. Monitoring the reproducibility and the stability of a proteomics workflow based on LC-MS and LC MS/MS signal" *In preparation* 

<u>E. Tsirogianni</u>, E. Chaput, E. Niesor, M. Karas, H. Langen & A. Ducret. "Protein characterization of Brush Border membranes of ApoE knockout: Is IBAT the missing link to hypercholesterolemia?" *In preparation* 

#### Patents:

<u>E. Tsirogianni</u> & A. Ducret (2007) "Method for purifying brush border membrane proteins" submitted for patent application, number EP 07108055.0.

#### **Oral Presentations:**

<u>E. Tsirogianni</u>, M. Karas, H. Langen & A. Ducret "Characterization of Brush Border membrane proteins of mice intestinal mucosa. Emphasis to the study of cholesterol absorption", oral presentation at the 6th international congress of the Swiss proteomic Society, Lausanne Switzerland, 3-5 Dec. 2007.

<u>E. Tsirogianni</u>, N. Berntenis, M. Karas, H. Langen & A. Ducret "Identification of Brush Border membrane proteins of mice intestinal mucosa. Emphasis to the study of cholesterol absorption", oral presentation at the 2nd international conference of the Hellenic Proteomic Society, Chania, Greece, 23-25 May. 2007.

# **Personal information**

Date of birth:	October 15, 1978
Citizenship:	Greek
Language skills:	native Greek speaker
	Fluent in English, oral and writing
	Basic knowledge in German and French

# Education

#### Johann Wolfgang Goethe University, Frankfurt-am-Main, Germany 2004-present

Institute of Pharmaceutical Chemistry under the joint of supervision of Prof. Dr. M. Karas (University of Frankfurt) and PD Dr. H. Langen (F. Hoffmann-La Roche Ltd). PhD. thesis in the field of Proteomics "Membrane Proteomics: Characterization of Brush Border membrane proteins of mice intestinal mucosa. Case study: cholesterol absorption".

# **University of Crete, Heraklion, Greece**

Chemistry Department under the supervision of Prof. Dr. G. Tsiotis Masters of Science in Biochemistry "Study of the metabolic pathway of phenol degradation by a new strain of pseudomonas PhDV1"

#### **University of Crete, Heraklion, Greece**

Chemistry Department under the supervision of Prof. Dr. G. Tsiotis Diploma work in BioAnalytical Chemistry: "Isolation and biochemical characterization of vitellogenin from the organism *Sparidae aurata*" Overall GPA: 8.66/10 with mention "excellent".

#### 2001-2003

1997-2001

# **Research and Working experience**

# F. Hoffmann-La Roche Ltd, PDP, Basel, Switzerland

Trainee Global Project Manager in Pharma Development. Coordinator and facilitator of a Life Cycle Team.

# F.Hoffmann-La Roche Ltd, PRG-RCMG, Basel, Switzerland

Coordinator for a joint project between the RCMG-Biology Research group and the Center of Biotechnology group of DSM Nutritional Products Ltd (in parallel to my PhD. work). Evaluation and development of quantitative methods using stable isotope labeling for the comparison of protein expression levels in bacterial strains using mass spectrometry.

# F. Hoffmann-La Roche Ltd, PRG-RCMG, Basel, Switzerland

Trainee in research and technology development in the field of mass spectrometry. Evaluation and automatisation of the LIFT process in the Bruker Ultraflex II MALDI TOF mass spectrometer.

Supervisor: Dr A. Ducret

# Novartis AG, Department of Immunology and Transplantation, Basel, Switzerland 2003

Trainee in the field of immunology and transplantation. Evaluation of O-GlcNAc versus phosphorylation of proteins in activated Jurkat T-cells. Supervisor: Dr. A. Katopodis

#### **University of Crete, Department of Chemistry, Crete, Greece**

Preparation and set-up of the undergraduate biochemistry laboratory. Supervisor: Prof. Dr. D. Ganotakis

# University Hospital of Heraklion, Department of Clinical Pathology, Crete, Greece 2001

Internship in the field of clinical chemistry. Research in liver carcinogenesis from hepatitis B patients.

Supervisor: Prof. Dr. I. Diamantis

# University of Crete, Department of Chemistry, Crete, Greece 2000-2001

Researcher in the frame of the research program PENNED 99 of the Greek Secretariat for Research and Technology. Subject: "Regulatory mechanism of association and disassociation of the light harvesting complex LHCII of the photosystem II" Supervisor: Prof. Dr. G. Tsiotis

# **Teaching experience**

# University of Crete, Department of Chemistry, Crete, Greece2001-2003Supervision of three undergraduate students during their Diploma thesis2001-2003Laboratory assistant for the undergraduate Biochemistry laboratory (2 semesters)2002-2003Teaching assistant in the undergraduate biochemistry course (2 semesters)2001

#### Schlussgedanken

Eidesstattliche Versicherung

Ich erkläre hiermit an Eides hiermit an Eides Statt, dass ich die vorgelegte Dissertation über "Membrane Proteomics: Characterization of Brush Border membrane proteins of mice intestinal mucosa. Case study: cholesterol absorption" selbständig angefertigt und anderer Hilfsmittel als der in ihr angegebenen nicht bedient habe, insbesondere, dass aus Schriften Entlehnungen, soweit sie in der Dissertation nicht ausdrücklich als solche mit Angabe der betreffenden Schrift beyeichnet sind, nicht stattgefunden haben.

Frankfurt am Main, den .....
