## Synthesis of Thiophenylazobenzene

Chemicals were used as purchased from Sigma-Aldrich, Acros Organics, Alfa Aesar and TCI Europe. Anhydrous solvents were purchased from Acros Organics. Technical grade solvents used during workup and purification were distilled prior to use. Air and/or water-sensitive reactions were carried out under Schlenk-conditions. Solids were dried under high vacuum when necessary. Flash column chromatography and column chromatography was carried out with Silica 60 M (0.04 0.063 mm ) from Macherey Nagel GmbH \& Co. KG. Thin layer chromatography was carried out on Polygram® SIL G/UV254 from Macherey Nagel GmbH \& Co. KG. NMR spectra were measured on a Bruker Avance II 200 MHz , Avance II 400 MHz or Avance III 600 MHz spectrometer at room temperature. Chemical shifts are reported in parts per million (ppm) relative to the solvent peak, coupling constants (J) are reported in Hertz (Hz). Deuterated solvents were obtained from Deutero GmbH (Kastellaun, Germany) or Euriso - Top GmbH. For all azobenzenes, the thermodynamically more stable E-isomer is reported. ESI-MS spectra were performed on a Bruker Daltonics Micro TOF. Melting points were measured on a Krüss M5000 melting point meter.

Synthesis of 1-(thiophen-2-yl)-2-(p-tolyl)diazene 2.

Synthesis of 4-methylphenyldiazonium tetrafluoroborate. p-Toluidine ( $2.18 \mathrm{~g}, 20.1 \mathrm{mmol}, 1.00 \mathrm{eq}$.) was suspended in water $(10 \mathrm{~mL})$ and aq. $\mathrm{HBF}_{4}\left(50 \%, 8 . \mathrm{mL}, 64 \mathrm{mmol}, 3.2\right.$ eq.) was added. The suspension was cooled to $0{ }^{\circ} \mathrm{C}$ and a solution of $\mathrm{NaNO}_{2}\left(1.41 \mathrm{~g}, 20.4 \mathrm{mmol}, 1.01 \mathrm{eq}\right.$.) in water ( 5 mL ) was added dropwise. The suspension was vigorously stirred at $0^{\circ} \mathrm{C}$ for 45 min . Following, the precipitate was filtered off, washed with plenty of $\mathrm{Et}_{2} \mathrm{O}$ and was dried in vacuum to yield a pearly grey solid ( $3.22 \mathrm{~g}, 78 \%$ ). The product was used without further purification.

Azo coupling. To a solution of thiophene ( $1.2 \mathrm{~mL}, 15 \mathrm{mmol}, 1.0 \mathrm{eq}$.) in dry THF ( 15 mL ) under a nitrogen atmosphere, $n$ BuLi in hexanes ( 10 mL , ca. 1.6 M , 16 mmol , 1.1 eq.) was added dropwise at $0^{\circ} \mathrm{C}$. The orange solution was stirred at this themperature for 30 min and was then transferred dropwise to a suspension of 4 -methylphenyldiazonium tetrafluoroborate ( $2.99 \mathrm{~g}, 14.5 \mathrm{mmol}, 1.00 \mathrm{eq}$.) in dry THF ( 15 mL ) at $-78^{\circ} \mathrm{C}$ under $\mathrm{N}_{2}$. Following, the dark red solution was stirred while being allowed to warm to rt for 1 h . Afterwards, the reaction was quenched by adding sat. aq. $\mathrm{NaHCO}_{3}(30 \mathrm{~mL})$ and EtOAc $(50 \mathrm{~mL})$. After phase separation, the organic layer was washed with brine ( 50 mL ), was dried over $\mathrm{MgSO}_{4}$, filtered and the solvents were evaporated under reduced pressure. The residue was filtered over a silica plug (DCM wash), concentrated, and was purified by flash column chromatography $\left(\mathrm{SiO}_{2}\right.$, cyclohexane/EtOAc; 100:1, 50:1) to yield a brown to red solid, which was recrystallized from $\mathrm{EtOH} / \mathrm{H}_{2} \mathrm{O}$ (2:1) to yield a bronze or yellow crystalline solid (1.98 g, 67\%).
${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta / \mathrm{ppm}: 7.81-7.73(\mathrm{~m}, 3 \mathrm{H}), 7.38(\mathrm{dd}, \mathrm{J}=5.4,1.3 \mathrm{~Hz}, 1 \mathrm{H}), 7.30-7.27(\mathrm{~m}, 2 \mathrm{H}), 7.18-7.12(\mathrm{~m}$, 1H), 2.42 (s, 3H).
${ }^{13}$ C NMR (101 MHz, $\mathrm{CDCl}_{3}$ ) $\delta / \mathrm{ppm}: 160.7,150.3,141.5,131.2,129.9,128.1,127.5,123.0,21.7$
HRMS (ESI): m/z for $\mathrm{C}_{11} \mathrm{H}_{10} \mathrm{~N}_{2 \mathrm{~S}} \mathrm{Na}^{+}$; calcd. 225.0457, found 225.0461.
TLC $\left(\mathrm{SiO}_{2}\right.$, cyclohexane/EtOAc; 9:1): $\mathrm{R}_{\mathrm{f}}=0.45$.
m.p. $113^{\circ} \mathrm{C}$.
${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectra

## Stationary UV/vis experiments

The steady state absorption spectra and the irradiation experiments were performed in acetonitrile and using a standard spectrophotomer (Specord S600, Analytik Jena). The PSS were generated as follows: i) PSS ${ }_{365}$ was achieved by using a 365 nm LED (ThorLabs M365L2); ii) the $\mathrm{PSS}_{285}$ was achieved by using a 285 nm LED (ThorLabs M285L5). The QY of the $E \rightarrow Z$ isomerization after $\pi \pi^{*}$ excitation of the compounds was determined approximately using the above mentioned spectrophotometer and LEDs and as described in ref. ${ }^{[1]}$

## UV/vis pump-probe

The setup for time-resolved transient absorption measurements was described previously in detail. ${ }^{[1]}$ It consists of an oscillator/amplifier system (Clark, MXR-CPA-iSeries, $1 \mathrm{kHz}, 775 \mathrm{~nm} 150 \mathrm{fs}$ ) which provides the ultrashort laser fundamental pulses. These pulses are then used to drive a home-built two stage NOPA (noncollinear optical parametric amplifier) ${ }^{[2]}$ system and a sum frequency generation stage to produce the excitation pulses used in the experiments. These NOPA pulses were pre-compressed using a prism compressor placed between the two NOPA stages. In addition, part of the laser fundamental was focused into a $\mathrm{CaF}_{2}$-crystal ( 5 mm ) to generate light continuum for the probe pulses. The cross-correlation between the excitation pulses and the probe pulses was $\sim 100$ fs. The signal was detected in reference mode by two spectrometers ( 600 lines $/ \mathrm{mm}$ gratings, blazed at 300 nm , and a 64-channel photodiode array). Anisotropic contributions were eliminated by measuring under magic angle conditions ( $54.7^{\circ}$ pump-probe polarization difference). The experiments were carried out in a fused silica cuvette with 1 mm optical path length, which was continuously moved to ensure fresh sample volume for each laser excitation pulse. In addition, the sample was continuously irradiated with a 285 nm LED for the ( $E$ )-isomer experiments and with a 365 nm LED for the ( $Z$-isomer experiments to prevent accumulation of the opposite isomer during the experiments. The 365 nm LED irradiation results in dominant population ( $\sim 90 \%$ ) of the ( $Z$ )-isomer, so that the $Z \rightarrow E$ experiments can be conducted at 445 nm excitation.

## Data analysis

The analysis of the experimental data was performed using OPTIMUS (www.optimusfit.org). ${ }^{[3]}$ Lifetime distribution analysis (LDA) was used for the ultrafast transient absorption data as a model independent method of analysis that naturally deals with non-exponential or distributed kinetics. In this analysis, the pre-exponential amplitudes of a set of 100 exponential functions with fixed, equally spaced (on a decimal logarithm scale) lifetimes are determined. The obtained pre-exponential amplitudes at each detection wavelength can be presented in the form of a contour lifetime density map (LDM) ${ }^{[4]}$. The transient absorption data around time zero position contain the so-called coherent artifact contributions. These were approximated with a function composed of a Gaussian and/or its first and second derivative ${ }^{[3,5]}$ and fitted within the same routine as the exponential fitting.

## Computational details

The ground state geometries for two possible TphAB in both ( $E$ )- and (Z)-configurations were optimized by employing density functional theory (DFT/BHLYP) ${ }^{[6]}$. Time-dependent DFT ${ }^{[7]}$ has proved to be able to reproduce accurate excited state calculations for $A B$ derivatives ${ }^{[8]}$. Using time-dependent DFT in combination with conductor-like polarizable continuum model (C-PCM) ${ }^{[9]}$ for acetonitrile solvation $(\varepsilon=37.5)$, we performed electronic structure and excitation energy calculations of TphAB and computed their UV/vis absorption spectra at the BHLYP/6-31+G*[10] level of theory. We used the algebraic diagrammatic construction scheme $(\operatorname{ADC}(2))^{[11]}$ to benchmark the results of TDDFT calculations. To simulate the $E \rightarrow Z$, $Z \rightarrow E$ isomerization process, Tamm-Dancoff approximation (TDA) ${ }^{[12]}$ and the state-tracking technique ${ }^{[13]}$ was applied to the unconstrained geometry optimization of ( $E$ )- and ( $Z$ )-TphAB-1. In most cases, the $6-31+\mathrm{G}^{*}$ basis set was adopted, while a smaller basis set $6-31 \mathrm{G}^{*}$ was used in the unconstrained geometry optimization. In the case of $E \rightarrow Z$ direction, the uncontained optimization converges to a local minimum at CNNC of $116^{\circ}$ due to the present of a barrier on the potential energy surface. From this point, constrained optimizations were carried out for CNNC between $116^{\circ}$ and $90^{\circ}$ to reach the conical intersection with the grounds state. From CNNC $90^{\circ}$, again unconstrained optimization was carried out in the ground state. All calculations were performed with the Q-Chem $5.0^{[14]}$ package.

Figure S2. Detachment (red) and attachment (blue) densities for the lowest excited states at the TDDFT/BHLYP/6-31G* level of theory for the stable ground state geometries of the $(E)$ - and ( $Z$ )-isomer of the studied ThpAB. The detachment density corresponds to that part of the density that is removed upon excitation, while the attachment density is the one that is added.

Figure S3. Calculated excitation energies at the ADC level of theory for the stable ground state geometries of the ( $E$ )- and ( $Z$ )-isomer of the studied ThpAB.

Figure S4. Calculated excitation energies at the BHLYP level of theory for the stable ground state geometries of the ( $(E)$ - and ( $Z$ )-isomer of the studied ThpAB.

Figure S5. (A) Experimental absorption spectra of the ( $\left(\right.$ E)-isomer, the $\mathrm{PSS}_{365}$ and the estimated pure ( $Z$ )-isomer spectra. Note that the (Z)-isomer spectrum is determined based on the highest possible contribution of the ( $E$-isomer to the PSS365 spectrum (i.e. 3.2\%). (B) Calculated spectra at the ADC level of theory for the $(E)$ - and the ( $Z$ )-isomer of ThpAB. Note that the calculated spectra are a weighted sum of the contribution from the two stable ground state geometries. Therefore, the $(E)$-isomer spectrum is a sum of $99.46 \%$ of $(E)$-TphAB- 1 and $0.54 \%$ of ( $E$ )-TphAB-2, while the $(Z)$-isomer spectrum is a sum of $97.25 \%$ of $(Z)$-TphAB-1 and $2.75 \%$ of $(Z)$-TphAB-2.

Figure S6. Transient spectra at selected points in time representing the spectral evolution in acetonitrile of (E)-TphAB after 355 nm excitation (A) and of ( $Z$ )-TphAB after 455 nm excitation (B).

Figure S7. Potential energy curves for the torsion around one of the $N=N$ double bonds in $T p h A B$ calculated for the $S_{1}$ optimized geometry at fixed values of the CNNC dihedral angle. Model 1 (TphAB-1) and model 2 (TphAB-2) correspond to the stable ground state geometries 1 and 2 (see figures above)

Figure S8. Potential energy curves obtained from the unconstrained/partially constrained optimization of ( $E$ )-TphAB-1 started from the FranckCondon region on $\mathrm{S}_{1}$. Note: NNC is the angle on the benzene side ( $\mathbf{A}$ ), while CNN is the angle on the thiophene side of the molecule (B).

Figure S9. Potential energy curves obtained from the unconstrained optimization of (Z)-TphAB-1 started from the Franck-Condon region on $\mathrm{S}_{1}$. Note: NNC is the angle on the benzene side (A), while CNN is the angle on the thiophene side of the molecule (B).
