Supplement of

Remote monitoring of seismic swarms and the August 2016 seismic crisis of Brava, Cabo Verde, using array methods

Carola Leva et al.

S1 Array configuration and array transfer function

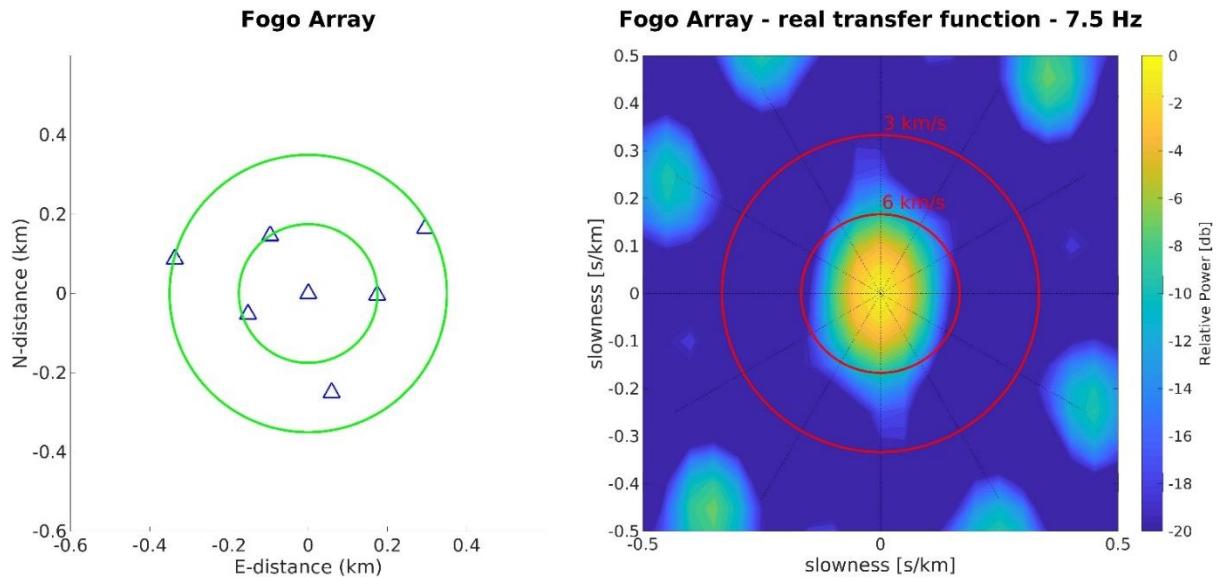

Figure S1: Left: configuration of the array which was operated from October 2015 to December 2016. Green circles: diameter of 700 m and 350 m. Triangles: short period 4.5-Hz geophone stations. Right: resulting array transfer function for signals with a frequency of 7.5 Hz. Red circles: apparent velocities of 3 km/s and 6 km/s which represent the range of expected apparent velocities of incoming wavefronts from local events

S2 Temporal evolution of the b -value

To analyze the temporal evolution of the b -value we split the study period into five 3-month long periods (Fig. S2). Apart from the period from April to June 2016 (Fig. S2c), the b -values do not show a significant variation, compared to the uncertainties of the b -value determination. In the period of April to June 2016 many events occur offshore, south of Brava. However, to explain this drop in the b -value and for a more detailed interpretation we would need a longer time span of observation, i.e. probably several years.

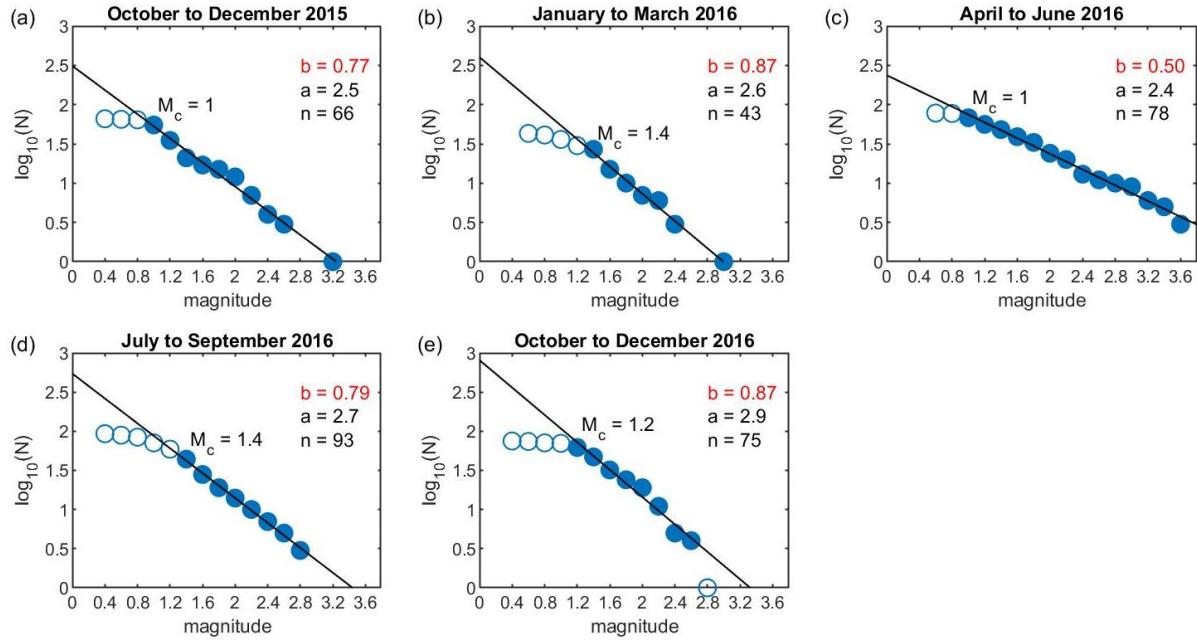

Figure S2: Magnitude–frequency relation for earthquakes observed during (a) October to December 2015, (b) January to March 2016, (c) April to June 2016, (d) July to September 2016, and (e) October to December 2016. Magnitudes are binned in steps of 0.2 and n gives the number of events during the period shown. Values used to fit the straight line for the determination of a and b are marked with filled dots.

S3 Network configuration of the follow-up study from Jan. 2017 – Jan. 2018

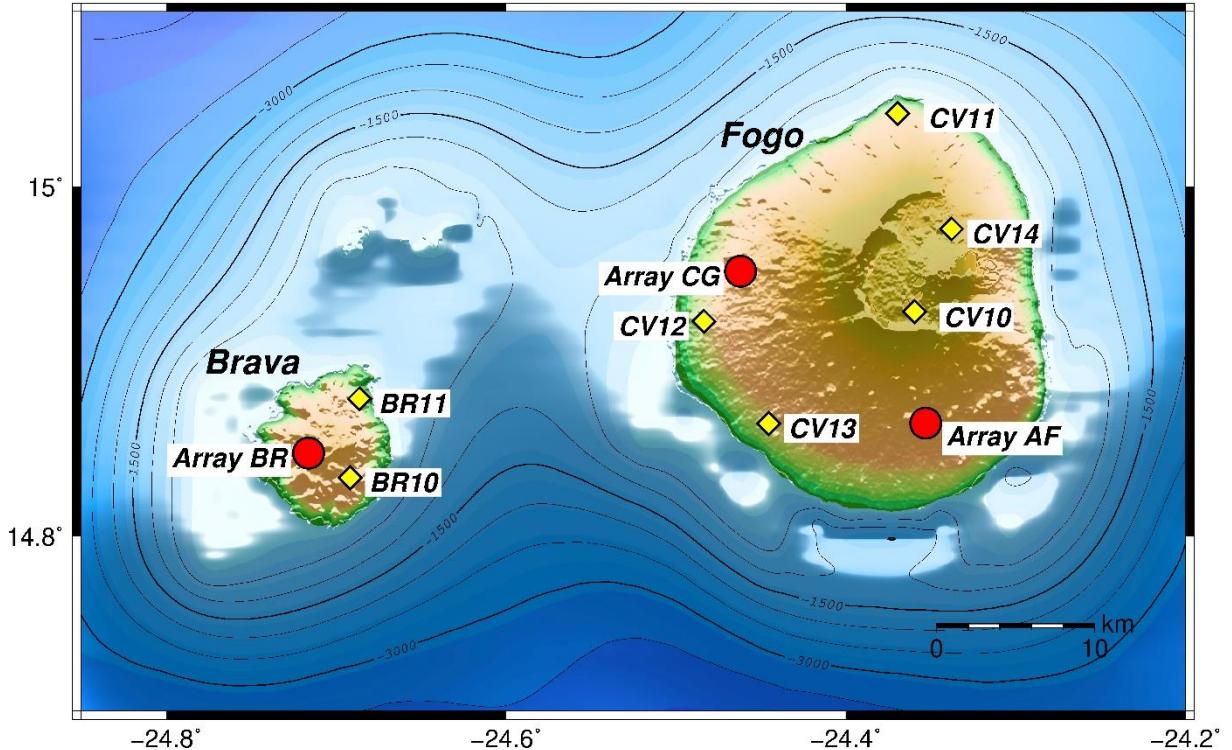

Figure S3: Station setup of the main study from January 2017 to January 2018. Red circles: arrays, yellow diamonds: short-period single stations. Topographic and bathymetry data are from Ryan et al. (2009).

S4 Aberration vectors of the array AF

To determine the aberration of the array used during the pilot study from October 2015 to December 2016, it is necessary to compare slowness and backazimuth values to those from earthquakes with otherwise known locations (e.g. Schweitzer et al., 2012). In our main study in 2017 we installed two arrays on Fogo, one on Brava and additionally seven short-period single stations (five on Fogo, two on Brava). Each array was equipped with four broadband Trillium Compact sensors and six 4.5 Hz geophones. The array AF (Fig. S2) is located and shaped in the same way as the array used during the pilot study. To draw conclusions on the aberration of the array of the pilot study, it is thus useful to determine the aberration of array AF. We are especially interested in deducing the possible aberrations with respect to the slowness determination of events within our study area around Brava. For this purpose, we use the whole network of 2017 to locate events within the network, where the standard localization method based on the code HYPOCENTER (Lienert et al., 1986), can be applied. Additionally, the error and rms of the standard localization analysis must not exceed a certain level to ensure a sufficiently precise localization of the related event. These criteria are applied to 13 events from January 2017 to December 2017 for which the backazimuth and slowness values were determined. The slowness can be estimated using the velocity model of Vales et al. (2014) for Cape Verde that we modified so that the velocity increases in 0.1 km steps with depth. The angle of incidence at the source for each station is provided by the localization code. Now the ray path

is estimated by applying Snell's law, until it reaches the ray turning point. The velocity at this depth corresponds to the apparent velocity determined from the array analysis ($v_a = 1/|s|$).

Figure S3 shows the resulting aberration vectors. For events originating beneath Brava, the vectors show a mean deviation of the backazimuth of about 6.5° to the south.

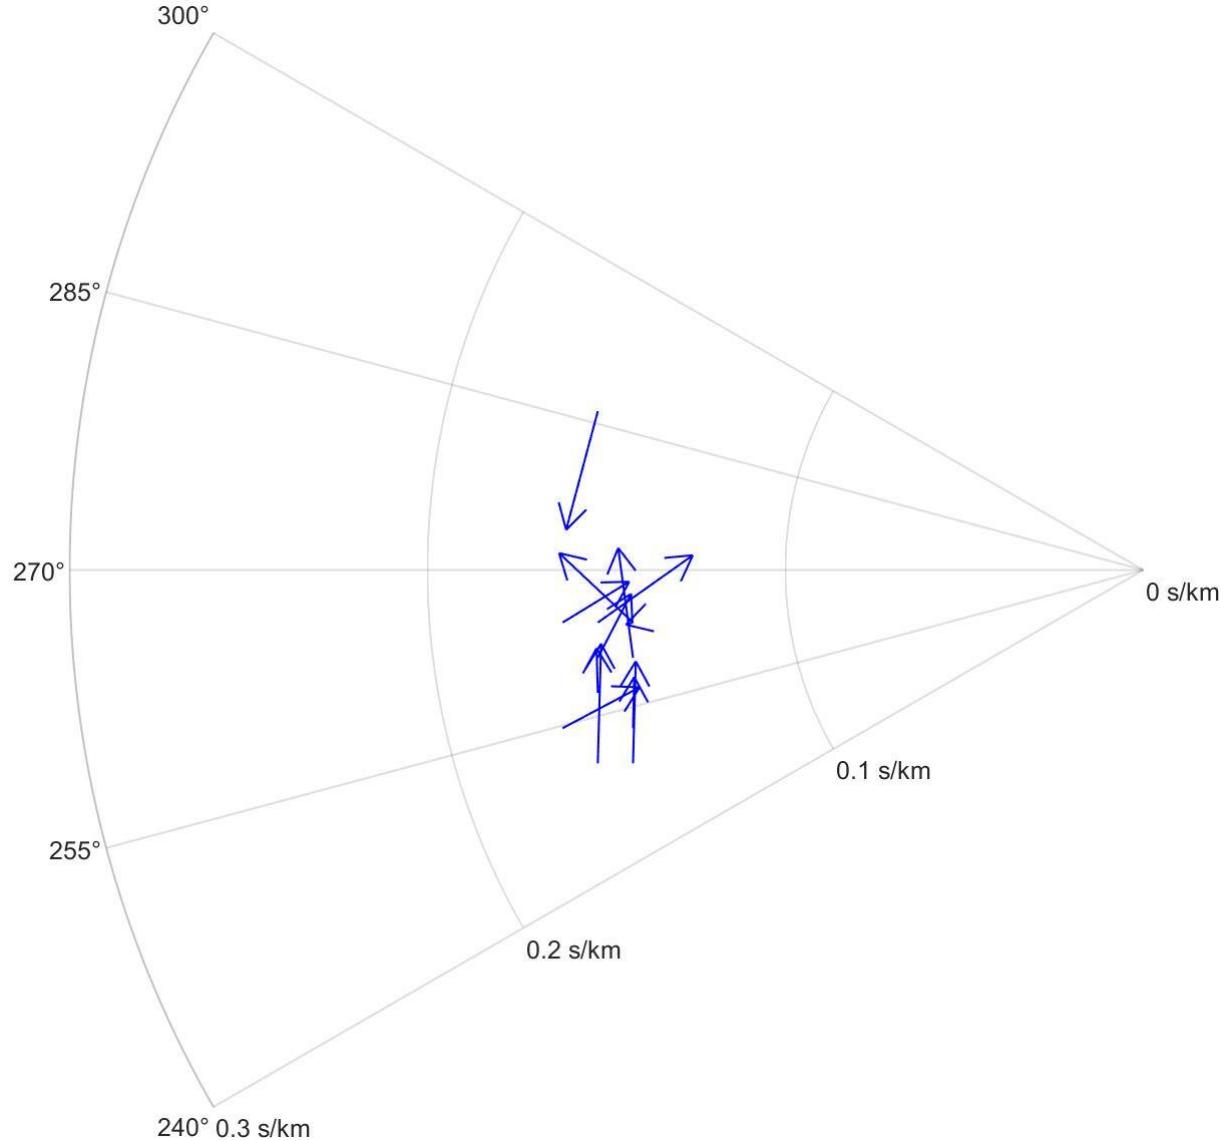

Figure S4: Aberration vectors of array AF deployed from January 2017 to January 2018 during the main study. Shape and location are the same for the array of the pilot study. Vectors are pointing from the backazimuth and slowness values of the array analysis to the respective values of the standard localization.

S5 Maps of earthquake locations and corresponding error ellipses

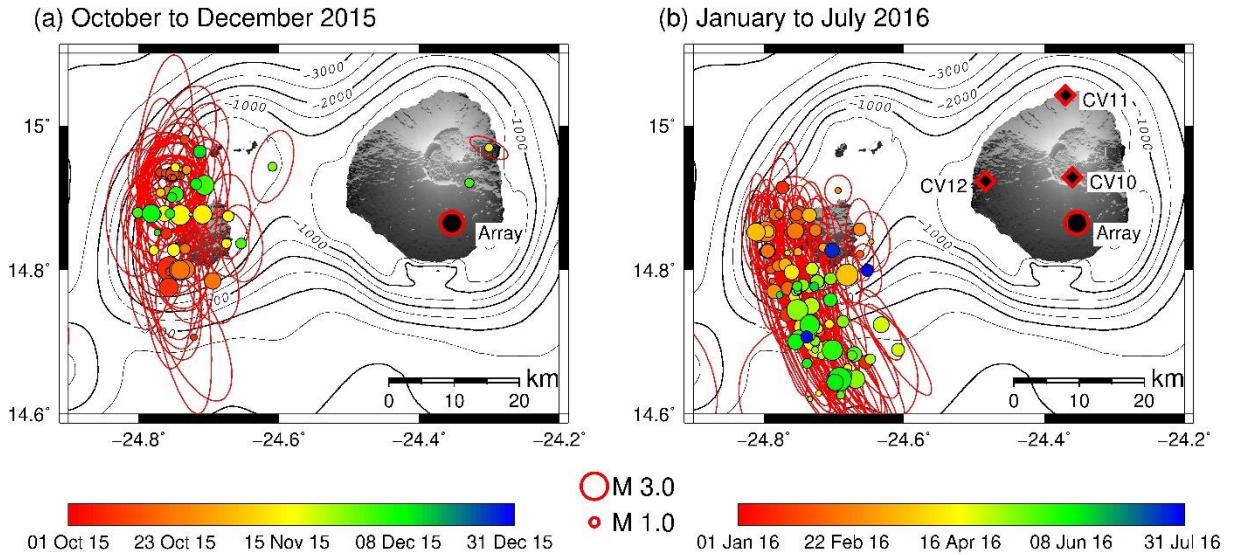

Figure S5.1: (a) Earthquake locations from 8 October to 19 December 2015. Red ellipses: errors in backazimuth and distance as determined for the array analysis. Red/black circle: position of the array on Fogo. (b) Earthquake locations from 15 January to 31 July 2016. Red ellipses: errors in backazimuth and distance as determined for the array analysis. Red/black circle: position of the array, red/black diamond: additional broadband stations on Fogo. Topographic and bathymetry data are from Ryan et al. (2009).

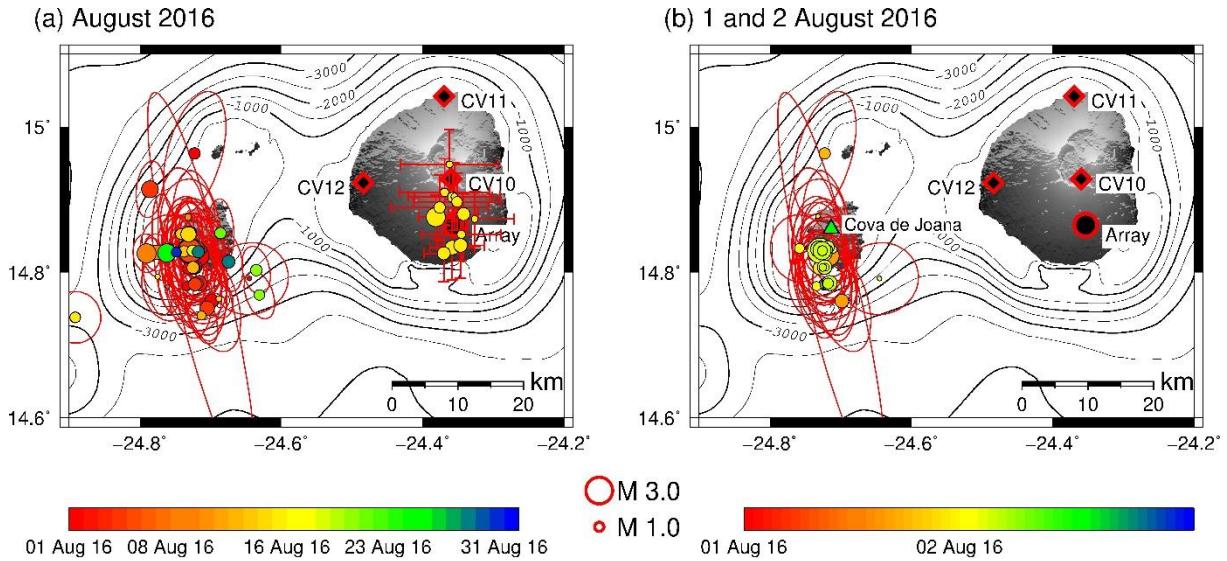

Figure S5.2: (a) Earthquake locations and error ellipses during August 2016, including the seismic crisis. Red ellipses: errors in backazimuth and distance as determined for the array analysis. Red/black circle: position of the array, red/black diamond: additional broadband stations on Fogo. (b) Earthquake locations during the seismic crisis on 1 and 2 of August 2016. Red ellipses: errors in backazimuth and distance as determined for the array analysis. Red/black circle: position of the array, red/black diamond: additional broadband stations on Fogo. Green triangle: village Cova de Joana, evacuated during the seismic crisis. Topographic and bathymetry data are from Ryan et al. (2009).

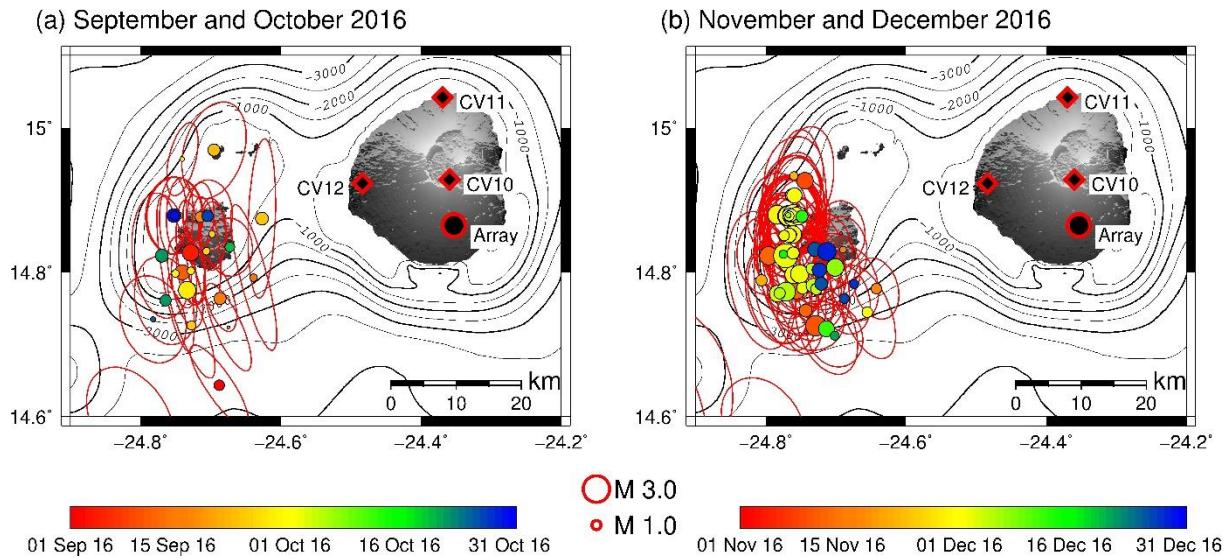

Figure S5.3: (a) Earthquake locations during September and October 2016. Red ellipses: errors in backazimuth and distance as determined for the array analysis. Red/black circle: position of the array, red/black diamond: additional broadband stations on Fogo. (b) The same for November and December 2016. Topographic and bathymetry data are from Ryan et al. (2009).
