J/ ψ production as a function of charged-particle multiplicity in p–Pb collisions at $\sqrt{s_{NN}} = 8.16$ TeV

ALICE Collaboration*

Abstract

Inclusive J/ ψ yields and average transverse momenta in p–Pb collisions at a center-of-mass energy per nucleon pair $\sqrt{s_{NN}} = 8.16$ TeV are measured as a function of the charged-particle pseudorapidity density with ALICE. The J/ ψ mesons are reconstructed at forward ($2.03 < y_{\text{cms}} < 3.53$) and backward ($-4.46 < y_{\text{cms}} < -2.96$) center-of-mass rapidity in their dimuon decay channel while the charged-particle pseudorapidity density is measured around midrapidity. The J/ ψ yields at forward and backward rapidity normalized to their respective average values increase with the normalized charged-particle pseudorapidity density, the former showing a weaker increase than the latter. The normalized average transverse momenta at forward and backward rapidity manifest a steady increase from low to high charged-particle pseudorapidity density with a saturation beyond the average value.

1 Introduction

Quarkonium states have long been considered as probes of the Quark–Gluon Plasma (QGP) produced in ultra-relativistic heavy-ion collisions [1]. The large color-charge density in the plasma prevents the formation of bound states, in an analogous process to the Debye screening for electromagnetic processes [2]. The suppression of J/ψ production in nucleus–nucleus (AA) with respect to proton–proton (pp) collisions was observed by several experiments [3–11]. To determine whether the origin of this suppression is the influence of the QGP or of Cold Nuclear Matter (CNM), data on proton(deuteron)–nucleus collisions are also scrutinized.

The measurements in p–Pb collisions at the LHC show a suppression of J/ψ production [12–14] at low transverse momentum (p_T) and forward center-of-mass rapidity (p-going direction, positive y_{cms}), consistent with various combinations of CNM effects: modification of the parton distribution functions (PDFs) in nuclei, i.e. shadowing [15, 16], the Color-Glass Condensate (CGC) [17, 18], or coherent parton energy loss [19]. The measurement of $\psi(2S)$ production in p–Pb collisions [20] exhibits a larger suppression than the one measured for J/ψ , both at forward and backward rapidity, which was not expected from CNM predictions. This effect is reproduced by models which consider the break-up of the bound quark–anti-quark pair via interactions with the final-state comoving particles [21, 22].

The p–Pb data at the center-of-mass energy per nucleon–nucleon collision of $\sqrt{s_{NN}} = 5.02$ TeV [23, 24] showed that these effects depend on the centrality of the collision, as estimated from the energy deposited in the Zero Degree Calorimeter in the Pb-going direction [25], and/or the produced charged-particle multiplicity [26]. An increase of the relative J/ψ and Υ [26–28] yields with the relative charged-particle multiplicity is observed, similarly to the results from pp collisions [27–29]. The increase of the J/ψ normalized yields was observed to be similar to the increase for D mesons [30, 31], suggesting that a common mechanism may be at its origin. The excited-to-ground state ratios, $\Upsilon(nS)/\Upsilon(1S)$, were found to decrease with increasing charged-particle multiplicity, which was not expected from CNM predictions [27, 28].

The measurements of two-particle angular correlations in small systems have shown interesting structures in the angular correlation function. A near-side ridge, located at $(\Delta\phi) \approx 0$, is observed in high-multiplicity pp [32] and p–Pb [33] collisions, accompanied by an away-side structure, located at $\Delta\phi \approx \pi$ and exceeding the away-side jet contribution, in p–Pb collisions [34, 35]. These structures are reminiscent of those in Pb–Pb data [36], interpreted as signatures of the collective motion of the particles during the hydrodynamic evolution of the hot and dense medium. Correlations of J/ψ (at large rapidity) and charged particles (at midrapidity) in p–Pb collisions [37, 38] revealed persisting long-range correlation structures at high p_T , similar to those observed with charged hadrons. The corresponding elliptic flow coefficients are found to be positive and of comparable magnitude to those measured in Pb–Pb collisions [39–41], indicating that the mechanism at its origin could be similar in both collision systems.

This letter reports the measurement of the multiplicity-differential inclusive J/ψ yield and average transverse momentum in p–Pb collisions at $\sqrt{s_{NN}} = 8.16$ TeV. The J/ψ mesons are reconstructed at forward and backward center-of-mass rapidities in their dimuon decay channel. The charged-particle pseudorapidity density is measured around midrapidity. It complements and extends previous J/ψ measurements performed as a function of the collision centrality and the charged-particle multiplicity at $\sqrt{s_{NN}} = 5.02$ TeV [23, 26]. The classification of events as a function of their charged-particle pseudorapidity density enables the scrutiny of rare events, corresponding to the 0.01–0.04% highest multiplicities in the collision. This allows p–Pb events to be studied from low multiplicities, similar to those of pp collisions, up to very large multiplicities corresponding to ~ 100 produced charged particles per rapidity unit, similar to those of peripheral Pb–Pb collisions, which exhibit collective-like effects.

2 Experimental setup and data samples

In this section, the detector subsystems relevant for this analysis are presented. A complete description of the ALICE detector and its performance can be found in [42, 43].

The muon spectrometer [42, 43] covers the pseudorapidity window of $-4.0 < \eta < -2.5$ and consists of: a 4 m long composite front absorber, corresponding to about 10 interaction lengths ($10 \lambda_{\text{int}}$), starting at 90 cm from the nominal interaction point, ten layers of muon tracking chambers (MCH), coupled to a dipole magnet with a 3 Tm field integral, and four layers of muon trigger chambers (MTR). The MCH and MTR systems are separated by an additional iron wall of about $7.2 \lambda_{\text{int}}$ that absorbs the remaining hadronic and low-momentum particle contamination. A rear absorber positioned downstream of the MTR filters out the background from beam-gas interactions. A conical absorber surrounds the beam pipe and protects the spectrometer against secondary particles produced mainly by large- η primary particles interacting with the beam pipe.

The Silicon Pixel Detector (SPD) [44] is the innermost part of the Inner Tracking System (ITS). It consists of two cylindrical silicon pixel layers at radial distances of 3.9 and 7.6 cm from the beam line. The respective pseudorapidity coverage of the two layers are $|\eta| < 2$ and $|\eta| < 1.4$. The SPD is used to reconstruct the primary vertex and to measure the charged-particle pseudorapidity density at midrapidity.

The V0 scintillator arrays [45] are located at each side of the interaction point, covering the pseudorapidity ranges of $-3.7 < \eta < -1.7$ and $2.8 < \eta < 5.1$. In this analysis, the V0 provides an online trigger and helps to reject contamination from beam-gas events.

The neutron Zero Degree Calorimeter (ZDC) [42] located at about 112.5 m on either side from the interaction point are used to reject electromagnetic interactions and beam-induced background.

The results presented in this letter are obtained with data recorded during the p–Pb run at $\sqrt{s_{\text{NN}}} = 8.16$ TeV in 2016. The J/ψ are reconstructed in the dimuon channel with data taken in two different beam configurations. Due to the asymmetry of the beam energy per nucleon in p–Pb collisions at the LHC, the nucleon–nucleon center-of-mass rapidity frame is shifted by $\Delta y = 0.465$ in the direction of the proton beam. As a consequence, the J/ψ are measured in the forward rapidity range of $2.03 < y_{\text{cms}} < 3.53$ (with protons going in the direction of the muon spectrometer, p-going direction) and in the backward rapidity region $-4.46 < y_{\text{cms}} < -2.96$ (Pb-going direction). Events used in this analysis were collected with a dedicated dimuon trigger which requires the coincidence of signals in both V0 arrays (minimum bias trigger, MB) with at least two opposite-sign muons registered in the MTR. The trigger has an adjustable online threshold, which for this data sample was set to only accept muons with transverse momenta $p_{\text{T}} > 0.5$ GeV/ c (p_{T} for which an efficiency of 50% is reached). The p_{T} differential single-muon trigger efficiency reaches a plateau of $\sim 96\%$ at $p_{\text{T}} \sim 1.5$ GeV/ c . In this data-taking period, the maximum pile-up probability was about 4%. A dedicated event-selection strategy—exploiting the signals in the V0 and the ZDC, the correlation of the number of clusters and track segments reconstructed in the SPD, as well as an algorithm to tag events with multiple vertices—allowed us to keep the pile-up below 0.5% for the analysed events, even at large multiplicities.

3 Charged-particle multiplicity measurement

The charged-particle pseudorapidity density ($dN_{\text{ch}}/d\eta$) is measured at midrapidity exploiting the information provided by the SPD detector [46, 47]. It is evaluated by counting the number of tracklets (N_{tracklet}), i.e. track segments joining pairs of hits in the two layers of the SPD pointing to the primary vertex. The primary vertex is also computed with the SPD information. To minimize non-uniformities in the SPD acceptance, only events with a z -vertex position determined within $|z_{\text{vtx}}| < 10$ cm are considered, and tracklets are counted within $|\eta| < 1$.

The raw N_{tracklet} counts are corrected ($N_{\text{tracklet}}^{\text{corr}}$) for the variation of the detector conditions with time (fraction of active SPD channels) and its limited acceptance as a function of z_{vtx} using a data-driven event-by-event correction [29, 30]. In this analysis, the correction is done by renormalising the $N_{\text{tracklet}}(z_{\text{vtx}})$ distributions to the overall maximum with a Poissonian smearing to account for the fluctuations. The events are sliced in $N_{\text{tracklet}}^{\text{corr}}$ intervals. Monte Carlo (MC) simulations using the DPMJET [48] event generator and the GEANT3 transport code [49] are used to estimate $dN_{\text{ch}}/d\eta$ from $N_{\text{tracklet}}^{\text{corr}}$. A second order polynomial correlation is assumed between these two quantities for the full $N_{\text{tracklet}}^{\text{corr}}$ interval. Several sources of systematic uncertainty were taken into account. Possible deviations from the second order polynomial correlation were estimated by using other functions to quantify the correlation or MC averages in each interval, with values ranging from 0.1% at intermediate multiplicities to 6.9% (5.8%) at the lowest (highest) multiplicity intervals. The systematic uncertainty on the residual z_{vtx} dependence due to differences between data and MC amounts to 3%. Finally, the event generator influence was considered and evaluated by comparing the DPMJET simulations with events generated in EPOS [50], resulting in a 2% uncertainty.

The average charged-particle pseudorapidity density, $\langle dN_{\text{ch}}/d\eta \rangle$, in non-single diffractive (NSD) events was obtained from an independent analysis and amounts to $\langle dN_{\text{ch}}/d\eta \rangle = 20.33 \pm 0.83$ (20.32 ± 0.83) in p–Pb (Pb–p) collisions for $|\eta| < 1$ [47], where the quoted uncertainty is systematic.

Table 1 summarizes the contributions to the normalized charged-particle multiplicity uncertainty.

Table 1: Sources of systematic uncertainties on the normalized charged-particle multiplicity.

Source	$ \eta < 1$
$N_{\text{tracklet}}^{\text{corr}}$ to $dN_{\text{ch}}/d\eta$ correlation	0.1 – 6.9(5.8)%
z -vertex dependence	3%
Monte Carlo event generator	2%
$\langle dN_{\text{ch}}/d\eta \rangle$	4%

4 J/ψ measurement

The normalized J/ψ yield, i.e. the yield in each multiplicity interval i normalized to the multiplicity-integrated value, is evaluated as

$$\frac{dN^i/dy}{\langle dN/dy \rangle} = \frac{N_{J/\psi}^i N_{\text{MB}}^{\text{eq}} (A\epsilon)_{J/\psi} \epsilon_{\text{MB}}^i}{N_{J/\psi} N_{\text{MB}}^{i,\text{eq}} (A\epsilon)_{J/\psi}^i \epsilon_{\text{MB}}}, \quad (1)$$

from the reconstructed number of J/ψ , $N_{J/\psi}$, the number of minimum bias (MB) events equivalent to the analysed dimuon sample, $N_{\text{MB}}^{\text{eq}}$, the J/ψ acceptance and efficiency correction, $(A\epsilon)_{J/\psi}$, and the NSD event selection efficiency in the minimum bias sample, ϵ_{MB} .

The J/ψ are reconstructed for each multiplicity interval by combining opposite-sign muons and computing the invariant mass of the pairs. The muon identification is ensured by requiring that the track candidates reconstructed in the MCH have a matching track segment in the MTR. Furthermore, the individual tracks must fulfill the following criteria to make sure they are within the acceptance of the spectrometer: their radial distance from the beam axis at the end of the front absorber is within $17.6 < R_{\text{abs}} < 89.5$ cm and their pseudorapidity in the detector reference frame is within $-4 < \eta < -2.5$.

To extract the signal, the invariant-mass distributions are first corrected for the J/ψ acceptance times efficiency ($A\epsilon$), differentially in p_{T} and y . The resulting distributions are then fitted with a superposition of J/ψ and $\psi(2S)$ signals and a background lineshape. Various combinations of lineshapes are used in order to evaluate the signal counts and their uncertainties. The two charmonium resonances are parametrized by a sum of either two Crystal Ball or two pseudo-Gaussian functions with power-law

tails [51]. The tail parametrizations are fixed to the values determined from either fits of the J/ψ signal from MC simulations or to values taken from fits to the multiplicity-integrated distribution in p–Pb data at $\sqrt{s_{NN}} = 8.16$ TeV [13] and in pp data at $\sqrt{s} = 13$ TeV [52]. The tails obtained from fitting the multiplicity-integrated distributions using the Crystal Ball function are also considered, and fixed in the binned fits. The J/ψ peak mean position and width are left free in the multiplicity-integrated fit, whilst the ψ(2S) ones are bound to those of the J/ψ following the same procedure as in [53]. Note that the ψ(2S) yields obtained are not physical values, as the invariant-mass spectrum is corrected by the A&E correction for the J/ψ. In the multiplicity-differential fits, the mass and width of the J/ψ peak are fixed to the integrated values to ensure the convergence of the fits in the few cases where statistical significance is low. The background is parameterized by either a sum of two exponentials or the product of an exponential and a fourth-order polynomial. Two fit mass ranges are taken into account when computing the average number of J/ψ and its uncertainty: $1.7 < m_{\mu\mu} < 4.8$ GeV/c² and $2.0 < m_{\mu\mu} < 5.0$ GeV/c². Examples of fits at low, intermediate, and high multiplicity for data in the rapidity range $2.03 < y_{\text{cms}} < 3.53$ are shown in Fig. 1. The signal lineshape is found to be independent of multiplicity, while the background

Figure 1: Opposite-sign muon pair invariant mass distributions for selected multiplicity intervals, corrected for the J/ψ acceptance and efficiency, at forward rapidity. The distributions are shown together with a typical fit function (solid line, see text for details). The J/ψ signal contribution is also depicted by a dot-dashed red line, and the background by a dotted line.

does change with multiplicity. Therefore, in order to minimize the uncertainty on the signal extraction, the same signal lineshape is used in the fit function for both the numerator and denominator in Eq. 1.

The number of equivalent MB events N_{MB}^{eq} is computed from the number of dimuon triggered events, $N_{\mu\mu}$, and the normalization factor of dimuon triggered to MB events (calculated as explained in next section) as $N_{MB}^{eq} = F_{norm} \cdot N_{\mu\mu}$. The number needs to be corrected for by the NSD event selection efficiency, $\epsilon_{MB} = (97 \pm 1)\%$ [47], to take into account the fraction of events without a reconstructed SPD vertex that are rejected. This factor ϵ_{MB} is found to be independent of the charged-particle multiplicity in all the intervals studied, with the exception of the lowest multiplicity interval, where it decreases by 1%.

The J/ψ acceptance and efficiency correction is obtained from MC simulations as a function of p_T and y_{cms} . The J/ψ are generated using p_T and y_{cms} distributions tuned to data [13]. They are simulated to decay into a muon pair using EvtGen [54]. The final state radiation is described with PHOTOS [55]. The acceptance and efficiency correction is independent of multiplicity in the measurement intervals. Therefore, when estimating the uncertainty on the MC input, only the possible variation of the input p_T and y_{cms} distributions is taken into account by using as input a subsample of the lower/higher multiplicity events.

To extract the J/ψ mean transverse momentum $\langle p_T^{J/\psi} \rangle$, the $A\epsilon$ -corrected transverse momentum of the dimuon pair is fitted with the following function [26]:

$$\begin{aligned} \langle p_T^{\mu\mu} \rangle(m_{\mu\mu}) &= \alpha^{J/\psi}(m_{\mu\mu}) \langle p_T^{J/\psi} \rangle \\ &+ \alpha^{\psi'}(m_{\mu\mu}) \langle p_T^{\psi'} \rangle \\ &+ \left(1 - \alpha^{J/\psi}(m_{\mu\mu}) - \alpha^{\psi'}(m_{\mu\mu})\right) \langle p_T^{bkgd} \rangle(m_{\mu\mu}), \end{aligned} \quad (2)$$

where the ratios of signal over the sum of signal and background of the two charmonium states $\alpha^{J/\psi} = S^{J/\psi}/(S^{J/\psi} + S^{\psi'} + B)$ and $\alpha^{\psi'} = S^{\psi'}/(S^{J/\psi} + S^{\psi'} + B)$ are fixed to the value extracted from fitting the invariant-mass spectrum corrected by the J/ψ $A\epsilon$. The background is described by a function $\langle p_T^{bkgd} \rangle(m_{\mu\mu})$. Two functional forms are used: either a sum of two exponentials or the product of an exponential and a fourth-order polynomial. Note that the $\langle p_T^{\psi'} \rangle$ does not represent a physical mean transverse momentum of the $\psi(2S)$ as the spectra are corrected by the $A\epsilon$ for J/ψ . Figure 2 illustrates typical $\langle p_T^{\mu\mu} \rangle$ distributions for selected multiplicity intervals.

Figure 2: Average transverse momentum of opposite-sign muon pairs for selected multiplicity intervals, corrected for the J/ψ acceptance and efficiency. The distributions are shown together with a typical fit function (see text for details).

5 Systematic uncertainties

The following sources of systematic uncertainty on the J/ψ yields in multiplicity classes are considered: (i) the signal extraction, (ii) the normalisation, (iii) the effect of resolution and pile-up, (iv) the event-by-event N_{tracklet} to $N_{\text{tracklet}}^{\text{corr}}$ correction, and (v) the event selection efficiency of the NSD event class. For the measurement of the yields in each multiplicity interval normalized to the event average, the systematic uncertainties are estimated directly for this ratio. Details on the signal extraction uncertainty were addressed in the previous section. The values are estimated by varying the signal and background shapes of the fit function, as well as by varying the invariant-mass range of the fit. The systematic uncertainty is computed as the root-mean-square of the uncertainties on the ratio for each of these fits, ranging between 0.8–2.3% (0.5–1.9%) at forward (backward) rapidity, being larger at large multiplicities where the number of events is smaller. The normalisation factor of the dimuon triggered to MB events F_{norm} is studied using three alternative methods [13]. The first method evaluates the probability of a coincidence of a dimuon- and a MB-triggered event in a MB-triggered data set. The second method exploits the higher probability of occurrence of a single-muon trigger by looking at the product of the probability of coincidence of a single-muon- and MB-triggered event and of the probability of finding a dimuon event in the single-muon triggered data. The third method is based on information from the trigger scalars. The run-by-run spread of the $F_{\text{norm}}/F_{\text{norm}}^i$ values computed for these three methods determines a 2.5% systematic uncertainty, independent of multiplicity. The effect of the method of choice for the event-by-event correction from N_{tracklet} to $N_{\text{tracklet}}^{\text{corr}}$ on the J/ψ yield is also studied [29, 30]. Both the randomisation function (Poisson or binomial) and the reference normalisation of the correction are varied. The Poissonian smearing is applied when the maximum is selected as normalisation reference, while the binomial correction should be used when considering all other possible reference values (in our case the minimum). The influence of these modifications on the yield ranges from 0.1% to 2.6% (4.3%) at forward (backward) rapidity, as a function of multiplicity. The uncertainty coming from pile up and multiplicity axis resolution is estimated as a single contribution by repeating the analysis multiple times with a different randomisation seed for the event-by-event correction, or introducing a small shift of the $N_{\text{tracklet}}^{\text{corr}}$ intervals, or varying the pile-up rejection criteria. The uncertainty amounts to 2%, independent of multiplicity. The uncertainty on the event selection efficiency for the NSD event class is estimated as in Ref. [47]. The uncertainty amounts to 1% and is correlated in all multiplicity intervals. Table 2 summarizes all contributions to the systematic uncertainty on the normalized yield.

For the $\langle p_T \rangle$, the effects of the uncertainty on the $\langle p_T \rangle$ extraction procedure and of the $A\mathcal{E}$ are considered. Similar to the yields, the signal extraction uncertainty is estimated by varying the fit function and its range. In addition, as the $S/(S+B)$ terms in Eq. 2 are fixed in the fit to the $\langle p_T \rangle$ invariant-mass spectrum, the influence of the statistical uncertainty on the J/ψ signal S is introduced via a Gaussian smearing of S (with respect to its statistical uncertainty) to prevent artificially minimising the uncertainty. It ranges from 0.2% to 3.0% (1.2%) at forward (backward) rapidity, increasing with multiplicity as a consequence of the smaller number of events. The uncertainty on the absolute $\langle p_T \rangle$ also takes into account the uncertainty on: (i) the MC input shapes as a function of p_T and y_{cms} , ranging from < 0.1 to 6% (< 0.1 to 11%) at forward (backward) rapidity, (ii) the tracking efficiency, 1% [13], (iii) the trigger efficiency, 2.6% (3.1%) [13], and (iv) the matching efficiency between the tracks in the MCH and the MTR, 1% [13]. To evaluate the uncertainty on the MC input, the data are divided into two multiplicity classes at the mean of the $N_{\text{tracklet}}^{\text{corr}}$ distribution for each rapidity interval. For each of these bins, the $\langle p_T \rangle$ is estimated using a modified $A\mathcal{E}$ correction, which was re-weighted to better describe the p_T - and y -dependent distributions of J/ψ in given bin. The systematic uncertainty is taken as the difference of the original $\langle p_T \rangle$ value, computed with the initial $A\mathcal{E}$ correction, and the new $\langle p_T \rangle$ estimated with re-weighted correction. The uncertainty on all the measured multiplicity intervals is extrapolated from these two values assuming that in each class the uncertainty is proportional to the $\langle p_T \rangle$. The contributions of the tracking, the trigger and their matching to the uncertainty are correlated between multiplicity intervals. The normalized $\langle p_T \rangle$ values are only affected by the uncertainty on the signal extraction procedure and the MC input,

which is partly correlated in multiplicity and ranges from $< 0.1\%$ to 2% ($< 0.1\%$ to 4%) in the forward (backward) rapidity interval. Table 3 summarizes all contributions to the average and normalized average p_{T} measurements.

Table 2: Sources of systematic uncertainties on the normalized yield. The contributions marked with an asterisk are correlated in multiplicity.

6 Results and discussion

The normalized J/ψ yield, at forward and backward rapidities, is presented in Fig. 3 as a function of the normalized charged-particle pseudorapidity density, measured at midrapidity ($|\eta| < 1$). The yield increases with increasing multiplicity in both rapidity intervals. The yield at backward rapidity grows faster than the one at forward rapidity, reaching values above those expected from a linear (with slope unity) increase at large multiplicities. On the other hand, at forward rapidity the values show a slower-than-linear increase at large multiplicities. The forward and backward rapidity yields cross a linear increase estimate (and each other) at around 1.5 times the average multiplicity. The underlying mechanism remains unclear. The forward (p-going) rapidity region probes the Pb-nucleus low Bjorken- x regime ($x_{\text{Pb}} \sim 10^{-5}$ in a naive 2-body calculation for $p_{\text{T}} = 0$), whereas the backward (Pb-going) rapidity is sensitive to the intermediate-to-large values ($x_{\text{Pb}} \sim 10^{-2}$). The observed suppression of the p_{T} - and multiplicity-integrated J/ψ yield at forward rapidity is described by different cold nuclear matter models considering the probed shadowing/saturation domain [13]. The centrality-differential measurements at $\sqrt{s_{\text{NN}}} = 5.02$ TeV [23] of the nuclear modification factor, $\langle p_{\text{T}} \rangle$ and $\langle p_{\text{T}}^2 \rangle$, corresponding to relative multiplicities of at most 2.5 times the average one, can also be described by these models.

The normalized J/ψ yield is compared with the one measured in p–Pb collisions at $\sqrt{s_{\text{NN}}} = 5.02$ TeV [26] in Fig. 4. Good agreement is found for both rapidity intervals. These results extend the probed charged-particle pseudorapidity density interval, both at low and high multiplicity, examining events of up to almost six times the average value. The more precise $\sqrt{s_{\text{NN}}} = 8.16$ TeV data evidence a continuous increase with multiplicity up to the largest multiplicities attained. The similarities at $\sqrt{s_{\text{NN}}} = 8.16$ TeV and $\sqrt{s_{\text{NN}}} = 5.02$ TeV suggest a common origin of the multiplicity trend, with a mechanism whose effect varies with rapidity, but might have a small dependence on the collision energy. This is consistent with the large variation of the probed x_{Pb} with rapidity and its relative slow evolution on the collision energy (typically a factor of 2 in the simplified 2-body picture).

Figure 3: Normalized yield of inclusive J/ψ, at forward and backward rapidities, as a function of the normalized charged-particle pseudorapidity density, measured at midrapidity, in p–Pb collisions at $\sqrt{s_{\text{NN}}} = 8.16$ TeV. The vertical bars represent the statistical uncertainties. The vertical and horizontal widths of the boxes represent the respective systematic uncertainties for the J/ψ yields and the multiplicities. The dashed line indicates the diagonal line, to guide the eye.

Figure 4: Normalized yield of inclusive J/ψ as a function of the normalized charged-particle pseudorapidity density, measured at midrapidity, in p-Pb collisions at $\sqrt{s_{NN}} = 8.16$ TeV and $\sqrt{s_{NN}} = 5.02$ TeV [26]. The top (bottom) panel presents the measurement at forward (backward) rapidity. The vertical bars represent the statistical uncertainties, the boxes the systematic ones. The dashed line indicates the diagonal line, to guide the eye.

Figure 5 presents a comparison of the normalized J/ψ p–Pb yields with results from pp collisions at $\sqrt{s_{NN}} = 7$ TeV [29] ($2.5 < y_{cms} < 4.0$) and Pb–Pb collisions at $\sqrt{s_{NN}} = 5.02$ TeV [56] ($2.5 < y_{cms} < 4.0$). The ratio of the yields over the corresponding charged-particle multiplicity is also shown in Fig. 5. The trend exhibited by the pp data is similar to the one observed in the backward (Pb-going) direction.

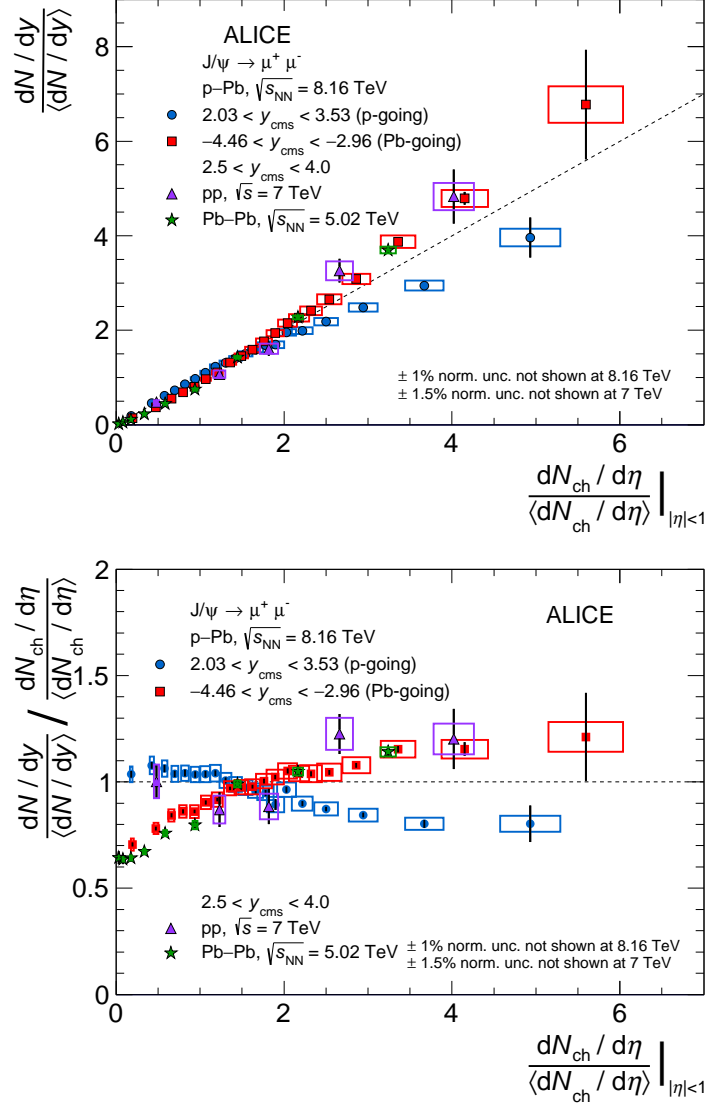

Figure 5: Top: Normalized yield of inclusive J/ψ as a function of the normalized charged-particle pseudorapidity density, measured at midrapidity, in various collision systems. Bottom: Ratio of the normalized yields to the corresponding normalized charged-particle pseudorapidity density. The pp results are normalized to INEL collisions [29], whereas p–Pb ones refer to the NSD event class; all for $p_T > 0$. The Pb–Pb data points include J/ψ with $0.3 < p_T < 12$ GeV/ c to reduce the low- p_T contribution from photoproduction, which is significant only in more peripheral collisions [56–58]. The vertical bars represent the statistical uncertainties, the boxes the systematic ones. The dashed line indicates the diagonal line, to guide the eye.

It should be noted that the pp results are normalized to the inelastic ‘INEL’ event class, whereas the p–Pb measurements are normalized to the non-single-diffractive ‘NSD’ one. In p–Pb collisions these two event classes mostly overlap when comparing MB results [47]. The Pb–Pb data also show a faster-than-linear increase with the normalized charged-particle pseudorapidity density. They are compatible within uncertainties with the p–Pb backward rapidity result in the restricted multiplicity interval of the measurement. Whereas the pp and p–Pb data include J/ψ with $p_T > 0$, the Pb–Pb data points include J/ψ

with $0.3 < p_T < 12$ GeV/ c to reduce the low- p_T contribution from photoproduction, which is significant only in more peripheral collisions [56–58].

The measured yield in p–Pb collisions can be described with the EPOS 3 event generator [59, 60] (see Fig. 6) based on a combination of Gribov-Regge theory and pQCD: where the individual scatterings are identified with parton ladders emerging as flux tubes, the existence of multiple nucleon–nucleon collisions in pPb collisions is accounted for, the initial conditions of the collision are modified due to CNM effects including parton saturation, and slow string segments (far from the surface) can be further mapped to fluid dynamic fields using a core-corona description. The J/ψ bound-state formation in EPOS 3 assumes a color-evaporation approach, i.e. it is associated to a charm quark–anti-quark pair in a given mass range. The influence of the viscous hydrodynamic evolution of the bulk in the EPOS 3 calculation is small (see Fig. 6). However the number of simulated events at large multiplicities is limited and does not allow us to elucidate possible hydrodynamic effects.

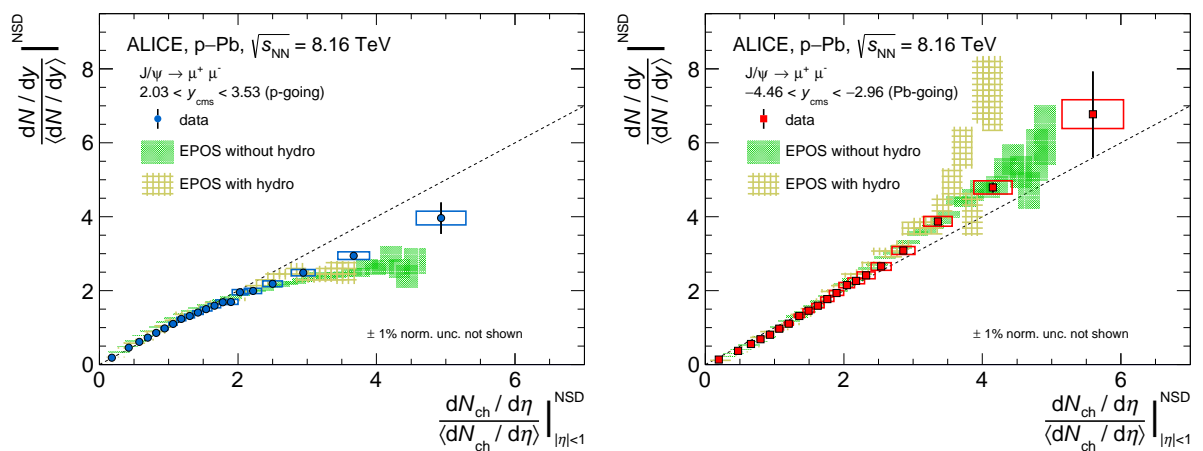

Figure 6: Normalized yield of inclusive J/ψ as a function of the normalized charged-particle pseudorapidity density, measured at midrapidity, in p–Pb collisions at $\sqrt{s_{NN}} = 8.16$ TeV compared with EPOS 3 [59, 60] calculations. Left (right) panel presents the measurement at forward (backward) rapidity. The vertical bars represent the statistical uncertainties, the boxes the systematic ones. The dashed line indicates the diagonal line, to guide the eye. The shaded areas represent the statistical uncertainties on the EPOS 3 calculations.

Figure 7 presents $\langle p_T \rangle$ as a function of the relative charged-particle pseudorapidity density. The measured $\langle p_T \rangle$ is systematically smaller at backward than at forward rapidity. This is also true for the multiplicity-integrated value, which is consistent with the observed decrease of $\langle p_T \rangle$ with increasing $|y_{cms}|$ in pp collisions [61]. The $\langle p_T \rangle$ increases steadily for multiplicities below the average, and saturates above the average multiplicity. Two naive scenarios are typically considered to explain high-multiplicity events: the incoherent superposition of multiple parton–parton collisions, or single parton interactions with higher energy transfer. One would expect the latter to be characterized by a higher $\langle p_T \rangle$ of the produced J/ψ . Reality is probably somewhere in between these two simplified scenarios. The simultaneous increase of the yield together with the saturation of $\langle p_T \rangle$ may point to J/ψ production from an incoherent superposition of parton–parton collisions, as suggested by two-particle correlation studies [62].

A comparison of the normalized $\langle p_T \rangle$ at $\sqrt{s_{NN}} = 8.16$ TeV and $\sqrt{s_{NN}} = 5.02$ TeV [26] as a function of the normalized charged-particle pseudorapidity density is shown in Fig. 8. The measurements are in remarkable agreement, within the uncertainties, at both energies and rapidities confirming that the mechanism governing J/ψ production and its variation with the charged-particle pseudorapidity density has small or no variation with the collision energy, in the explored interval.

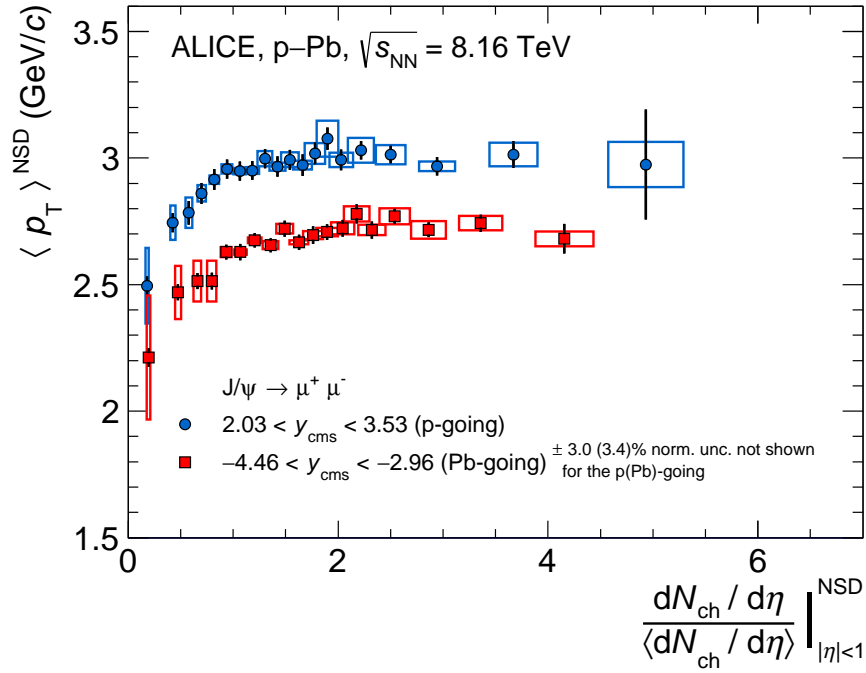

Figure 7: Average transverse momentum of inclusive J/ψ at forward and backward rapidities as a function of the normalized charged-particle pseudorapidity density, measured at midrapidity, in p–Pb collisions at $\sqrt{s_{\text{NN}}} = 8.16$ TeV. The vertical bars represent the statistical uncertainties, the boxes the systematic ones.

7 Conclusions

The production of inclusive J/ψ at large rapidities in p–Pb collisions at $\sqrt{s_{\text{NN}}} = 8.16$ TeV is reported as a function of the charged-particle pseudorapidity density at midrapidity. The normalised J/ψ yield shows an increase with increasing normalised charged-particle pseudorapidity density. The yield at backward rapidity grows faster than the forward rapidity one, reaching values above those of the linear (with slope unity) increase estimate at large normalised multiplicity, whereas the values at forward rapidity show a slower-than-linear increase. The trends of the normalised yield are reproduced by the EPOS 3 [59, 60] event generator. The $\langle p_T \rangle$ is smaller at backward than at forward rapidity, consistent with the expected softening of the spectra with increasing $|y_{\text{cms}}|$. The $\langle p_T \rangle$ increases steadily for multiplicities below the average, and saturates above the average multiplicity. The simultaneous increase of the yield together with the saturation of $\langle p_T \rangle$ may point to J/ψ production from an incoherent superposition of parton–parton collisions, as suggested by two-particle correlation studies [62]. These measurements show trends compatible with those observed at $\sqrt{s_{\text{NN}}} = 5.02$ TeV [26], but in this work an improved precision and extended multiplicity coverage were reached. The similarities suggest a common origin, with a mechanism whose effect varies with rapidity, but with only a small dependence (if any) on the collision energy.

Figure 8: Normalized average transverse momentum of inclusive J/ψ as a function of the normalized charged-particle pseudorapidity density, measured at midrapidity, in p-Pb collisions at $\sqrt{s_{NN}} = 8.16$ TeV and $\sqrt{s_{NN}} = 5.02$ TeV [26]. Top (bottom) panel presents the measurement at forward (backward) rapidity. The vertical bars represent the statistical uncertainties, the boxes the systematic ones.

Acknowledgements

The ALICE Collaboration would like to thank all its engineers and technicians for their invaluable contributions to the construction of the experiment and the CERN accelerator teams for the outstanding performance of the LHC complex. The ALICE Collaboration gratefully acknowledges the resources and support provided by all Grid centres and the Worldwide LHC Computing Grid (WLCG) collaboration. The ALICE Collaboration acknowledges the following funding agencies for their support in building and running the ALICE detector: A. I. - 8 Centro de Aplicaciones Tecnológicas y Desarrollo Nuclear (CEADEN), Havana, Cuba
- 9 Centro de Investigación y de Estudios Avanzados (CINVESTAV), Mexico City and Mérida, Mexico
- 10 Centro Fermi - Museo Storico della Fisica e Centro Studi e Ricerche “Enrico Fermi”, Rome, Italy
- 11 Chicago State University, Chicago, Illinois, United States
- 12 China Institute of Atomic Energy, Beijing, China
- 13 Comenius University Bratislava, Faculty of Mathematics, Physics and Informatics, Bratislava, Slovakia
- 14 COMSATS University Islamabad, Islamabad, Pakistan
- 15 Creighton University, Omaha, Nebraska, United States
- 16 Department of Physics, Aligarh Muslim University, Aligarh, India
- 17 Department of Physics, Pusan National University, Pusan, Republic of Korea
- 18 Department of Physics, Sejong University, Seoul, Republic of Korea
- 19 Department of Physics, University of California, Berkeley, California, United States
- 20 Department of Physics, University of Oslo, Oslo, Norway
- 21 Department of Physics and Technology, University of Bergen, Bergen, Norway
- 22 Dipartimento di Fisica dell’Università ‘La Sapienza’ and Sezione INFN, Rome, Italy
- 23 Dipartimento di Fisica dell’Università and Sezione INFN, Cagliari, Italy
- 24 Dipartimento di Fisica dell’Università and Sezione INFN, Trieste, Italy
- 25 Dipartimento di Fisica dell’Università and Sezione INFN, Turin, Italy
- 26 Dipartimento di Fisica e Astronomia dell’Università and Sezione INFN, Bologna, Italy
- 27 Dipartimento di Fisica e Astronomia dell’Università and Sezione INFN, Catania, Italy
- 28 Dipartimento di Fisica e Astronomia dell’Università and Sezione INFN, Padova, Italy
- 29 Dipartimento di Fisica ‘E.R. Caianiello’ dell’Università and Gruppo Collegato INFN, Salerno, Italy
- 30 Dipartimento DISAT del Politecnico and Sezione INFN, Turin, Italy
- 31 Dipartimento di Scienze e Innovazione Tecnologica dell’Università del Piemonte Orientale and INFN Sezione di Torino, Alessandria, Italy
- 32 Dipartimento di Scienze MIFT, Università di Messina, Messina, Italy
- 33 Dipartimento Interateneo di Fisica ‘M. Merlin’ and Sezione INFN, Bari, Italy
- 34 European Organization for Nuclear Research (CERN), Geneva, Switzerland
- 35 Faculty of Electrical Engineering, Mechanical Engineering and Naval Architecture, University of Split, Split, Croatia
- 36 Faculty of Engineering and Science, Western Norway University of Applied Sciences, Bergen, Norway
- 37 Faculty of Nuclear Sciences and Physical Engineering, Czech Technical University in Prague, Prague, Czech Republic
- 38 Faculty of Science, P.J. Šafárik University, Košice, Slovakia
- 39 Frankfurt Institute for Advanced Studies, Johann Wolfgang Goethe-Universität Frankfurt, Frankfurt, Germany
- 40 Fudan University, Shanghai, China
- 41 Gangneung-Wonju National University, Gangneung, Republic of Korea
- 42 Gauhati University, Department of Physics, Guwahati, India
- 43 Helmholtz-Institut für Strahlen- und Kernphysik, Rheinische Friedrich-Wilhelms-Universität Bonn, Bonn, Germany
- 44 Helsinki Institute of Physics (HIP), Helsinki, Finland
- 45 High Energy Physics Group, Universidad Autónoma de Puebla, Puebla, Mexico
- 46 Hiroshima University, Hiroshima, Japan
- 47 Hochschule Worms, Zentrum für Technologietransfer und Telekommunikation (ZTT), Worms, Germany
- 48 Horia Hulubei National Institute of Physics and Nuclear Engineering, Bucharest, Romania
- 49 Indian Institute of Technology Bombay (IIT), Mumbai, India
- 50 Indian Institute of Technology Indore, Indore, India
- 51 Indonesian Institute of Sciences, Jakarta, Indonesia
- 52 INFN, Laboratori Nazionali di Frascati, Frascati, Italy
- 53 INFN, Sezione di Bari, Bari, Italy
- 54 INFN, Sezione di Bologna, Bologna, Italy
- 55 INFN, Sezione di Cagliari, Cagliari, Italy
- 56 INFN, Sezione di Catania, Catania, Italy
- 57 INFN, Sezione di Padova, Padova, Italy
- 58 INFN, Sezione di Roma, Rome, Italy

- 59 INFN, Sezione di Torino, Turin, Italy
- 60 INFN, Sezione di Trieste, Trieste, Italy
- 61 Inha University, Incheon, Republic of Korea
- 62 Institute for Nuclear Research, Academy of Sciences, Moscow, Russia
- 63 Institute for Subatomic Physics, Utrecht University/Nikhef, Utrecht, Netherlands
- 64 Institute of Experimental Physics, Slovak Academy of Sciences, Košice, Slovakia
- 65 Institute of Physics, Homi Bhabha National Institute, Bhubaneswar, India
- 66 Institute of Physics of the Czech Academy of Sciences, Prague, Czech Republic
- 67 Institute of Space Science (ISS), Bucharest, Romania
- 68 Institut für Kernphysik, Johann Wolfgang Goethe-Universität Frankfurt, Frankfurt, Germany
- 69 Instituto de Ciencias Nucleares, Universidad Nacional Autónoma de México, Mexico City, Mexico
- 70 Instituto de Física, Universidade Federal do Rio Grande do Sul (UFRGS), Porto Alegre, Brazil
- 71 Instituto de Física, Universidad Nacional Autónoma de México, Mexico City, Mexico
- 72 iThemba LABS, National Research Foundation, Somerset West, South Africa
- 73 Jeonbuk National University, Jeonju, Republic of Korea
- 74 Johann-Wolfgang-Goethe Universität Frankfurt Institut für Informatik, Fachbereich Informatik und Mathematik, Frankfurt, Germany
- 75 Joint Institute for Nuclear Research (JINR), Dubna, Russia
- 76 Korea Institute of Science and Technology Information, Daejeon, Republic of Korea
- 77 KTO Karatay University, Konya, Turkey
- 78 Laboratoire de Physique des 2 Infinis, Irène Joliot-Curie, Orsay, France
- 79 Laboratoire de Physique Subatomique et de Cosmologie, Université Grenoble-Alpes, CNRS-IN2P3, Grenoble, France
- 80 Lawrence Berkeley National Laboratory, Berkeley, California, United States
- 81 Lund University Department of Physics, Division of Particle Physics, Lund, Sweden
- 82 Nagasaki Institute of Applied Science, Nagasaki, Japan
- 83 Nara Women's University (NWU), Nara, Japan
- 84 National and Kapodistrian University of Athens, School of Science, Department of Physics, Athens, Greece
- 85 National Centre for Nuclear Research, Warsaw, Poland
- 86 National Institute of Science Education and Research, Homi Bhabha National Institute, Jatni, India
- 87 National Nuclear Research Center, Baku, Azerbaijan
- 88 National Research Centre Kurchatov Institute, Moscow, Russia
- 89 Niels Bohr Institute, University of Copenhagen, Copenhagen, Denmark
- 90 Nikhef, National institute for subatomic physics, Amsterdam, Netherlands
- 91 NRC Kurchatov Institute IHEP, Protvino, Russia
- 92 NRC Kurchatov Institute - ITEP, Moscow, Russia
- 93 NRNU Moscow Engineering Physics Institute, Moscow, Russia
- 94 Nuclear Physics Group, STFC Daresbury Laboratory, Daresbury, United Kingdom
- 95 Nuclear Physics Institute of the Czech Academy of Sciences, Řež u Prahy, Czech Republic
- 96 Oak Ridge National Laboratory, Oak Ridge, Tennessee, United States
- 97 Ohio State University, Columbus, Ohio, United States
- 98 Petersburg Nuclear Physics Institute, Gatchina, Russia
- 99 Physics department, Faculty of science, University of Zagreb, Zagreb, Croatia
- 100 Physics Department, Panjab University, Chandigarh, India
- 101 Physics Department, University of Jammu, Jammu, India
- 102 Physics Department, University of Rajasthan, Jaipur, India
- 103 Physikalisches Institut, Eberhard-Karls-Universität Tübingen, Tübingen, Germany
- 104 Physikalisches Institut, Ruprecht-Karls-Universität Heidelberg, Heidelberg, Germany
- 105 Physik Department, Technische Universität München, Munich, Germany
- 106 Politecnico di Bari, Bari, Italy
- 107 Research Division and ExtreMe Matter Institute EMMI, GSI Helmholtzzentrum für Schwerionenforschung GmbH, Darmstadt, Germany
- 108 Rudjer Bošković Institute, Zagreb, Croatia
- 109 Russian Federal Nuclear Center (VNIIEF), Sarov, Russia
- 110 Saha Institute of Nuclear Physics, Homi Bhabha National Institute, Kolkata, India

- 111 School of Physics and Astronomy, University of Birmingham, Birmingham, United Kingdom
- 112 Sección Física, Departamento de Ciencias, Pontificia Universidad Católica del Perú, Lima, Peru
- 113 St. Petersburg State University, St. Petersburg, Russia
- 114 Stefan Meyer Institut für Subatomare Physik (SMI), Vienna, Austria
- 115 SUBATECH, IMT Atlantique, Université de Nantes, CNRS-IN2P3, Nantes, France
- 116 Suranaree University of Technology, Nakhon Ratchasima, Thailand
- 117 Technical University of Košice, Košice, Slovakia
- 118 The Henryk Niewodniczanski Institute of Nuclear Physics, Polish Academy of Sciences, Cracow, Poland
- 119 The University of Texas at Austin, Austin, Texas, United States
- 120 Universidad Autónoma de Sinaloa, Culiacán, Mexico
- 121 Universidade de São Paulo (USP), São Paulo, Brazil
- 122 Universidade Estadual de Campinas (UNICAMP), Campinas, Brazil
- 123 Universidade Federal do ABC, Santo Andre, Brazil
- 124 University of Cape Town, Cape Town, South Africa
- 125 University of Houston, Houston, Texas, United States
- 126 University of Jyväskylä, Jyväskylä, Finland
- 127 University of Liverpool, Liverpool, United Kingdom
- 128 University of Science and Technology of China, Hefei, China
- 129 University of South-Eastern Norway, Tonsberg, Norway
- 130 University of Tennessee, Knoxville, Tennessee, United States
- 131 University of the Witwatersrand, Johannesburg, South Africa
- 132 University of Tokyo, Tokyo, Japan
- 133 University of Tsukuba, Tsukuba, Japan
- 134 Université Clermont Auvergne, CNRS/IN2P3, LPC, Clermont-Ferrand, France
- 135 Université de Lyon, Université Lyon 1, CNRS/IN2P3, IPN-Lyon, Villeurbanne, Lyon, France
- 136 Université de Strasbourg, CNRS, IPHC UMR 7178, F-67000 Strasbourg, France, Strasbourg, France
- 137 Université Paris-Saclay Centre d'Etudes de Saclay (CEA), IRFU, Département de Physique Nucléaire (DPhN), Saclay, France
- 138 Università degli Studi di Foggia, Foggia, Italy
- 139 Università degli Studi di Pavia, Pavia, Italy
- 140 Università di Brescia, Brescia, Italy
- 141 Variable Energy Cyclotron Centre, Homi Bhabha National Institute, Kolkata, India
- 142 Warsaw University of Technology, Warsaw, Poland
- 143 Wayne State University, Detroit, Michigan, United States
- 144 Westfälische Wilhelms-Universität Münster, Institut für Kernphysik, Münster, Germany
- 145 Wigner Research Centre for Physics, Budapest, Hungary
- 146 Yale University, New Haven, Connecticut, United States
- 147 Yonsei University, Seoul, Republic of Korea
