 (Received 23 July 2022; accepted 29 November 2022; published 26 December 2022)

Using 4.5 fb^{-1} of e^+e^- annihilation data samples collected at the center-of-mass energies ranging from 4.600 GeV to 4.699 GeV with the BESIII detector at the BEPCII collider, a first study of the semileptonic decays $\Lambda_c^+ \rightarrow pK^-e^+\nu_e$, $\Lambda_c^+ \rightarrow \Lambda(1520)e^+\nu_e$ and $\Lambda_c^+ \rightarrow \Lambda(1405)e^+\nu_e$ is performed. The $\Lambda_c^+ \rightarrow pK^-e^+\nu_e$ decay is observed with a significance of 8.2σ and the branching fraction is measured to be $\mathcal{B}(\Lambda_c^+ \rightarrow pK^-e^+\nu_e) = (0.88 \pm 0.17_{\text{stat}} \pm 0.07_{\text{syst}}) \times 10^{-3}$. We also report evidence of $\Lambda_c^+ \rightarrow \Lambda(1520)e^+\nu_e$ and $\Lambda_c^+ \rightarrow \Lambda(1405)e^+\nu_e$ with significances of 3.3σ and 3.2σ , respectively, and measure $\mathcal{B}(\Lambda_c^+ \rightarrow \Lambda(1520)e^+\nu_e) = (1.02 \pm 0.52_{\text{stat}} \pm 0.11_{\text{syst}}) \times 10^{-3}$ and $\mathcal{B}(\Lambda_c^+ \rightarrow \Lambda(1405)[\rightarrow pK^-]e^+\nu_e) = (0.42 \pm 0.19_{\text{stat}} \pm 0.04_{\text{syst}}) \times 10^{-3}$. Combining these with the inclusive semileptonic Λ_c^+ branching fraction measured by BESIII, the relative fraction is determined to be $[\mathcal{B}(\Lambda_c^+ \rightarrow pK^-e^+\nu_e)/\mathcal{B}(\Lambda_c^+ \rightarrow Xe^+\nu_e)] = (2.1 \pm 0.4_{\text{stat}} \pm 0.2_{\text{syst}})\%$, which provides a clear confirmation that semileptonic Λ_c^+ decays are not saturated by the $\Lambda\ell^+\nu_\ell$ final state.

DOI: [10.1103/PhysRevD.106.112010](https://doi.org/10.1103/PhysRevD.106.112010)

The study of Λ_c^+ semileptonic (SL) decays provides valuable informations about weak and strong interactions in baryons containing a heavy quark. (Throughout this paper, charge-conjugate modes are implied unless explicitly noted.) Their decay rates depend on the weak quark mixing Cabibbo-Kobayashi-Maskawa (CKM) matrix [1] element $|V_{cs}|$ and strong interaction effects parametrized by form factors describing the hadronic transition between the initial and the final baryons. In comparison to experimental studies of SL decays in the charmed meson sector [2], rather few measurements exist of Λ_c^+ SL decays. No other exclusive SL decay except $\Lambda_c^+ \rightarrow \Lambda\ell^+\nu_\ell$ ($\ell = e, \mu$) has been reported to date [3,4]. In addition, a comparison of the branching fractions (BFs) for the exclusive decay $\Lambda_c^+ \rightarrow \Lambda\ell^+\nu_\ell$ and inclusive decay $\Lambda_c^+ \rightarrow Xe^+\nu_\ell$ shows that their ratio is close to one [5], which exhibits a different pattern compared with charm mesons [2,6,7]. For example, the BF of $D^{+(0)} \rightarrow \bar{K}^0(K^-)e^+\nu_e$ is much smaller than $\mathcal{B}(D^{+(0)} \rightarrow e^+X)$ [2]. Searching for unknown exclusive SL Λ_c^+ decay can provide important information to validate and understand this pattern. The decay $\Lambda_c^+ \rightarrow pK^-e^+\nu_e$ is one of the best suited channels to search for [8–13], as its final state is simple with a high detection efficiency, in comparison to decays such as $\Lambda_c^+ \rightarrow \Sigma\pi e^+\nu_e$ etc.

Since the ud diquark is a spectator, the SL $\Lambda_c^+ \rightarrow pK^-e^+\nu_e$ decay provides a perfect filter of isospin $I = 0$ meson-baryon states with almost no contamination from the $I = 1$ amplitude [9,14]. This provides an ideal platform to study the internal structure of exotic Λ^* states. Among these states, particular interest is concentrated on the $\Lambda(1405)$, in which the high-mass pole strongly couples to $\bar{K}N$ final-state [2]. The $\Lambda(1405)$ is considered as the

most striking state in understanding the spectrum of baryons with strangeness and has been continuously studied for more than 60 years since its theoretical prediction [15,16]. However, the nature of $\Lambda(1405)$ is still mysterious [17,18]. It is suggested to be a dynamically generated meson-baryon molecular state [9,16,19] or a three-quark uds bound state [8,10]. The decay of $\Lambda_c^+ \rightarrow \Lambda(1405)e^+\nu_e$ is expected to be a promising process to distinguish its structure because the predicted BF of the decay in the two hypotheses differ by a factor of roughly 100 times [8–10], as shown in Table I discussed later.

Furthermore, in heavy-baryon SL decays, most previous lattice quantum chromodynamics (LQCD) calculations are concentrated on the transition of $J^P = 1/2^+ \rightarrow J^P = 1/2^+$ [20–29], while the calculations regarding the transitions of $J^P = 1/2^+ \rightarrow J^P = 3/2^-$ are still very limited [30,31]. That is because the LQCD calculations in $1/2^+ \rightarrow 3/2^-$ are substantially more challenging due to the fact that the correlation functions for negative-parity baryons have more statistical noise than those for the lightest positive-parity baryons [32]. On the other hand, no experimental data is available to calibrate the calculations in $1/2^+ \rightarrow 3/2^-$ transitions [2]. Recently, LQCD extended the prediction on negative-parity baryons by performing the first calculation in $\Lambda_c^+ \rightarrow \Lambda(1520)\ell^+\nu_\ell$ [12,13] decays, under the approximation that the $\Lambda(1520)$ is a stable particle under the strong interaction because of its narrow width. An experimental measurement of $\Lambda_c^+ \rightarrow \Lambda(1520)e^+\nu_e$ will certainly provide a valuable check of the methodology applied in LQCD calculations, which is largely shared also with the calculations in Λ_b decays [13,30,31]. Comparison of the $\Lambda_c^+ \rightarrow \Lambda(1520)/\Lambda(1405)e^+\nu_e$ decay rates between measurement and theoretical predictions provides a necessary check of the calculations from the nonrelativistic quark model [10] and the constituent quark model [8].

In this paper, we perform the first study of the Λ_c^+ SL decay $\Lambda_c^+ \rightarrow pK^-e^+\nu_e$. We further search for SL decays of $\Lambda_c^+ \rightarrow \Lambda(1405)(\rightarrow pK^-)e^+\nu_e$ and $\Lambda_c^+ \rightarrow$

$\Lambda(1520)(\rightarrow pK^-)e^+\nu_e$, which are expected to represent the dominant components in $\Lambda_c^+ \rightarrow \Lambda^*e^+\nu_e$ decays [8,10], by investigating the pK^- invariant-mass spectrum in $\Lambda_c^+ \rightarrow pK^-e^+\nu_e$ data. The analysis is performed using data sets collected at BESIII with center-of-mass energies of $\sqrt{s} = 4.600, 4.612, 4.628, 4.641, 4.661, 4.682, 4.699$ GeV. The total integrated luminosity for these data sets is 4.5 fb^{-1} [33,34]. This is the largest data sample collected in e^+e^- collisions near the $\Lambda_c^+\bar{\Lambda}_c^-$ pair production threshold.

The construction and performance of the BESIII detector are described in detail in Ref. [35]. A GEANT4-based [36] Monte Carlo (MC) simulation package, which includes the geometric description of the detector and the detector response, is used to determine signal detection efficiencies and to estimate potential background contributions. Signal MC samples of $e^+e^- \rightarrow \Lambda_c^+\bar{\Lambda}_c^-$ with a Λ_c^+ baryon decaying to $pK^-e^+\nu_e$ or $\Lambda(1520)/\Lambda(1405)e^+\nu_e$ together with a $\bar{\Lambda}_c^-$ decaying to the analyzed hadronic decay mode described below are generated by KKMC [37] with EVTGEN [38], with initial-state radiation (ISR) [39] and final-state radiation (FSR) [40] effects included. The simulation of the SL decays $\Lambda_c^+ \rightarrow pK^-e^+\nu_e$ or $\Lambda_c^+ \rightarrow \Lambda(1405)/\Lambda(1520)e^+\nu_e$ is modeled with a phase-space generator. To study the possible peaking and combinatorial background contributions, inclusive MC samples consisting of open-charm states, radiative return to charmonium(-like) ψ states at lower masses and continuum processes of $q\bar{q}$ ($q = u, d, s$), along with Bhabha scattering, $\mu^+\mu^-$, $\tau^+\tau^-$ and $\gamma\gamma$ events are generated.

The first step of the analysis is the selection of ‘‘single-tag’’ (ST) events with a fully reconstructed $\bar{\Lambda}_c^-$ candidate. The $\bar{\Lambda}_c^-$ hadronic decay modes used in this analysis are $\bar{\Lambda}_c^- \rightarrow \bar{p}K_S^0$, $\bar{p}K^+\pi^-$, $\bar{p}K_S^0\pi^0$, $\bar{p}K^+\pi^-\pi^0$, $\bar{p}K_S^0\pi^+\pi^-$, $\bar{\Lambda}\pi^-$, $\bar{\Lambda}\pi^-\pi^0$, $\bar{\Lambda}\pi^-\pi^+\pi^-$, $\bar{\Sigma}^0\pi^-$, $\bar{\Sigma}^-\pi^0$, $\bar{\Sigma}^-\pi^+\pi^-$, $\bar{p}\pi^+\pi^-$, $\bar{\Sigma}^0\pi^+\pi^-\pi^-$, and $\bar{\Sigma}^0\pi^-\pi^0$, where the intermediate particles K_S^0 , $\bar{\Lambda}$, $\bar{\Sigma}^0$, $\bar{\Sigma}^-$, and π^0 are reconstructed via their decays: $K_S^0 \rightarrow \pi^+\pi^-$, $\bar{\Lambda} \rightarrow \bar{p}\pi^+$, $\bar{\Sigma}^0 \rightarrow \gamma\bar{\Lambda}$ with $\bar{\Lambda} \rightarrow \bar{p}\pi^+$, $\bar{\Sigma}^- \rightarrow \bar{p}\pi^0$, and $\pi^0 \rightarrow \gamma\gamma$. Within this ST sample a search is then performed for $\Lambda_c^+ \rightarrow pK^-e^+\nu_e$ decay. The events passing this selection are referred to as the double-tag (DT) sample. For a specific tag mode i , the ST and DT event yields can be written as

$$N_{\text{ST}}^i = 2N_{\bar{\Lambda}_c\Lambda_c} \mathcal{B}_{\text{ST}}^i \epsilon_{\text{ST}}^i \quad \text{and} \quad N_{\text{DT}}^i = 2N_{\bar{\Lambda}_c\Lambda_c} \mathcal{B}_{\text{ST}}^i \mathcal{B}_{\text{SL}} \epsilon_{\text{DT}}^i,$$

where $N_{\bar{\Lambda}_c\Lambda_c}$ is the number of $\bar{\Lambda}_c\Lambda_c$ pairs; $\mathcal{B}_{\text{ST}}^i$ and \mathcal{B}_{SL} are the BFs of the $\bar{\Lambda}_c^-$ tag mode and the Λ_c^+ SL decay mode, respectively; ϵ_{ST}^i is the efficiency for finding the tag candidate; and ϵ_{DT}^i is the efficiency for simultaneously finding the tag $\bar{\Lambda}_c^-$ and the SL decay. The BF of the SL decay can be expressed as

$$\mathcal{B}_{\text{SL}} = \frac{N_{\text{DT}}}{\sum N_{\text{ST}}^i \times \epsilon_{\text{DT}}^i / \epsilon_{\text{ST}}^i} = \frac{N_{\text{DT}}}{N_{\text{ST}} \times \epsilon_{\text{SL}}}, \quad (1)$$

where N_{DT} is the total yield of DT events, N_{ST} is the total ST yield, and $\epsilon_{\text{SL}} = \frac{\sum N_{\text{ST}}^i \times \epsilon_{\text{DT}}^i / \epsilon_{\text{ST}}^i}{\sum N_{\text{ST}}^i}$ is the average efficiency for finding a SL decay weighted by the relative yields of tag modes in data.

Selection criteria for γ , π^\pm , K^\pm , $p(\bar{p})$ as well as the reconstruction of π^0 and K_S^0 candidates are the same as those used in Refs. [3,4]. The invariant masses $M_{\bar{p}\pi^+}$, $M_{\gamma\bar{\Lambda}}$, and $M_{\bar{p}\pi^0}$ are required to be within (1.110, 1.121) GeV/ c^2 , (1.179, 1.205) GeV/ c^2 , and (1.171, 1.204) GeV/ c^2 to form candidates of $\bar{\Lambda}$, $\bar{\Sigma}^0$, and $\bar{\Sigma}^-$, respectively.

The ST $\bar{\Lambda}_c^-$ signals are identified using the beam-constrained mass,

$$M_{\text{BC}} = \sqrt{(\sqrt{s}/2)^2/c^4 - |\vec{p}_{\bar{\Lambda}_c^-}|^2/c^2}, \quad (2)$$

where $\vec{p}_{\bar{\Lambda}_c^-}$ is the measured momentum of the ST $\bar{\Lambda}_c^-$. The energy difference $\Delta E = \sqrt{s}/2 - E_{\bar{\Lambda}_c^-}$ is defined to improve the signal significance for ST $\bar{\Lambda}_c^-$ baryons, where $E_{\bar{\Lambda}_c^-}$ is the measured energy. If more than one $\bar{\Lambda}_c^-$ tag is reconstructed in the event, only the tag with the minimum $|\Delta E|$ is kept to avoid double counting of STs with the same final state. The M_{BC} distributions at $\sqrt{s} = 4.682$ GeV for the fourteen ST modes are shown in Fig. 1. An unbinned maximum-likelihood fit is performed to the spectra, using the MC-simulated signal shape convolved with a Gaussian function accounting for differences of resolutions between data and MC simulation to describe the signal and an ARGUS function [41] to describe the background. The signal yield is determined in the mass region (2.28, 2.30) GeV/ c^2 , which is regarded as the signal region. The ΔE requirements, the M_{BC} distributions for the other data sets and their ST yields are documented in the Appendix A.

FIG. 1. Fits to the M_{BC} distributions for different ST modes at $\sqrt{s} = 4.682$ GeV. The points with error bars are data, the (red) solid curves show the total fits and the (blue) dashed curves are the fitted backgrounds.

The total ST yield reconstructed in the full data sample is $N_{ST} = 122268 \pm 474$, where only the statistical uncertainty is reported.

Candidates from $\Lambda_c^+ \rightarrow pK^-e^+\nu_e$ are selected from the remaining particles recoiling against the ST $\bar{\Lambda}_c^-$ candidates, with the requirement that there be exactly three charged tracks. To select protons and kaons, the same criteria as those used in the ST selection are used. The proton and kaon charges must be opposite in sign. Detection and reconstruction of the positron follow the procedures in Ref. [3]. Background from $\Lambda_c^+ \rightarrow pK^- \pi^+$ decays is rejected by requiring the pK^-e^+ invariant mass ($M_{pK^-e^+}$) to be less than 2.15 GeV/ c^2 . To suppress contamination from $\Lambda_c^+ \rightarrow pK^- \pi^+ \pi^0$ decays, a search is made for an additional π^0 in the recoiling system of the $\bar{\Lambda}_c^-$ baryon. If found, then a candidate $\Lambda_c^+ \rightarrow pK^- \pi^+ \pi^0$ decay is reconstructed, where the positron is now assigned a pion hypothesis. For the event to be retained, it is required that the beam-constrained mass of this candidate falls outside the signal region.

The energy and momentum carried by the neutrino are denoted by E_{miss} and \vec{p}_{miss} , respectively. They are calculated from the energies and momenta of the tag ($E_{\bar{\Lambda}_c^-}$, $\vec{p}_{\bar{\Lambda}_c^-}$) and the measured SL decay products ($E_{SL} = E_p + E_{K^-} + E_{e^+}$, $\vec{p}_{SL} = \vec{p}_p + \vec{p}_{K^-} + \vec{p}_{e^+}$) using the relations $E_{miss} = \sqrt{s}/2 - E_{SL}$ and $\vec{p}_{miss} = \vec{p}_{\Lambda_c^+} - \vec{p}_{SL}$ in the initial e^+e^- rest

FIG. 2. (Left) Fit to the U_{miss} distribution for $\Lambda_c^+ \rightarrow pK^-e^+\nu_e$ in data. (Right) The distribution of U_{miss} vs. M_{pK^-} for $\Lambda_c^+ \rightarrow pK^-e^+\nu_e$ candidates.

frame. Here, the momentum $\vec{p}_{\Lambda_c^+}$ is given by $\vec{p}_{\Lambda_c^+} = -\hat{p}_{tag} \sqrt{(\sqrt{s}/2)^2 - m_{\Lambda_c^-}^2}$, where \hat{p}_{tag} is the direction of the momentum of the ST $\bar{\Lambda}_c^-$ and $m_{\Lambda_c^-}$ is the known $\bar{\Lambda}_c^-$ mass [2]. Information about the undetected neutrino is obtained by using the variable U_{miss} ,

$$U_{miss} \equiv E_{miss} - c|\vec{p}_{miss}|. \quad (3)$$

The U_{miss} distribution is expected to peak at zero for the events of $\Lambda_c^+ \rightarrow pK^-e^+\nu_e$.

Figure 2 (left) shows the U_{miss} distribution of the reconstructed candidates for $\Lambda_c^+ \rightarrow pK^-e^+\nu_e$ in data. To obtain the signal yield, the U_{miss} distribution is described with four components: a signal function f which consists of a Gaussian to describe the core of the U_{miss} distribution and two power-law tails to account for initial- and final-state radiation [3,42], two MC-derived shapes describing components from $\Lambda_c^+ \rightarrow pK^- \pi^+ \pi^0$ and $\Lambda_c^+ \rightarrow pK^- \mu^+ \nu_\mu$, and an MC-derived nonresonant shape describing the combinatorial backgrounds. The yield of the $\Lambda_c^+ \rightarrow pK^- \mu^+ \nu_\mu$ component, $N_{DT}^{pK^- \mu^+ \nu_\mu}$, is related to $N_{DT}^{pK^- e^+ \nu_e}$, which is the yield of $\Lambda_c^+ \rightarrow pK^- e^+ \nu_e$ decay, by

$$N_{DT}^{pK^- \mu^+ \nu_\mu} = N_{DT}^{pK^- e^+ \nu_e} \times R_e \times R_B, \quad (4)$$

where $R_B = \frac{B(\Lambda_c^+ \rightarrow pK^- \mu^+ \nu_\mu)}{B(\Lambda_c^+ \rightarrow pK^- e^+ \nu_e)} = 0.88 \pm 0.03$ [10]. The uncertainty on R_B is evaluated by comparing the difference of the BF's of $\Lambda(1405)$ and $\Lambda(1520)$ resonances decaying into $N\bar{K}e^+\nu_e$ and $N\bar{K}\mu^+\nu_\mu$ final states. The parameter R_e , defined as the relative detection efficiency between $\Lambda_c^+ \rightarrow pK^- \mu^+ \nu_\mu$ and $\Lambda_c^+ \rightarrow pK^- e^+ \nu_e$, is evaluated to be 0.15 with MC simulation. The event yield for $\Lambda_c^+ \rightarrow pK^- e^+ \nu_e$, as determined from the fit to the U_{miss} distribution, is $N_{DT}^{pK^- e^+ \nu_e} = 33.5 \pm 6.3$, where the uncertainty is statistical. The statistical significance of the $\Lambda_c^+ \rightarrow pK^- e^+ \nu_e$ signal is determined to be 8.9σ , calculated via $\sqrt{-2 \times \Delta \ln \mathcal{L}}$, where $\Delta \ln \mathcal{L}$ is the variation in $\ln \mathcal{L}$ of the likelihood fit with and without the signal component included.

To search for $\Lambda_c^+ \rightarrow \Lambda(1520)/\Lambda(1405)e^+\nu_e$, the distribution of U_{miss} vs. M_{pK^-} is studied, as shown in Fig. 2 (right). An accumulation of events around the intersection of the $\Lambda(1520)/\Lambda(1405)$ and $pK^-e^+\nu_e$ signal regions is observed. To extract the yield of $\Lambda_c^+ \rightarrow \Lambda(1520)/\Lambda(1405)e^+\nu_e$, a two-dimensional (2D) likelihood fit is performed to the M_{pK^-} and U_{miss} distributions. For each component, the 2D distribution of M_{pK^-} and U_{miss} is modeled with a product of two one-dimensional probability density functions (PDFs), one for each dimension. The signal functions in the M_{pK^-} distribution for $\Lambda(1520)$ and $\Lambda(1405)$ are described by a Breit-Wigner (BW) function and a Flatté-parametrization [43], respectively. The masses and widths for $\Lambda(1520)$ and $\Lambda(1405)$ are fixed to the PDG values [2]. The M_{pK^-} distributions of the nonresonant (NR) components of $\Lambda_c^+ \rightarrow (pK^-)_{\text{NR}}e^+\nu_e$ and $\Lambda_c^+ \rightarrow pK^-\mu^+\nu_\mu$ are described with phase-space models, while for the components from $\Lambda_c^+ \rightarrow pK^-\pi^+\pi^0$ and the other background sources, the MC-derived shapes are used to describe the M_{pK^-} distributions. The U_{miss} distributions from $\Lambda_c^+ \rightarrow \Lambda(1520/1405)e^+\nu_e$ and $\Lambda_c^+ \rightarrow (pK^-)_{\text{NR}}e^+\nu_e$ decays are both described by the function f with parameters taken from MC simulation. For the other components, the shapes obtained from MC simulation are used. The projection of the 2D fit on the M_{pK^-} axis is shown in Fig. 3. The fitted DT yields for $\Lambda_c^+ \rightarrow \Lambda(1520)e^+\nu_e$ and $\Lambda_c^+ \rightarrow \Lambda(1405)e^+\nu_e$ are 8.4 ± 4.3 and 14.8 ± 6.7 , respectively, where the uncertainties are statistical only. The statistical significance of including only $\Lambda_c^+ \rightarrow \Lambda(1520)e^+\nu_e$ or $\Lambda_c^+ \rightarrow \Lambda(1405)e^+\nu_e$ is evaluated to be 3.8σ for both, with respect to the hypothesis that neither of the two states is included. It suggests that the two resonances contribute equally and neither of them can be neglected.

FIG. 3. Projection of the 2D-fit on the M_{pK^-} axis for $\Lambda_c^+ \rightarrow pK^-e^+\nu_e$ candidates in data.

The averaged efficiencies for detecting the $\Lambda_c^+ \rightarrow pK^-e^+\nu_e$, $\Lambda_c^+ \rightarrow \Lambda(1520)(\rightarrow pK^-)e^+\nu_e$ and $\Lambda_c^+ \rightarrow \Lambda(1405)(\rightarrow pK^-)e^+\nu_e$ decays are determined to be $\epsilon_{\text{SL}}^{pK^-e^+\nu_e} = (31.01 \pm 0.31)\%$, $\epsilon_{\text{SL}}^{\Lambda(1520)(\rightarrow pK^-)e^+\nu_e} = (30.03 \pm 0.31)\%$ and $\epsilon_{\text{SL}}^{\Lambda(1405)(\rightarrow pK^-)e^+\nu_e} = (28.64 \pm 0.32)\%$, respectively. Inserting the values of their DT yields, averaged efficiencies and N^{ST} into Eq. (1), results in $\mathcal{B}(\Lambda_c^+ \rightarrow pK^-e^+\nu_e) = (0.88 \pm 0.17 \pm 0.07) \times 10^{-3}$, $\mathcal{B}(\Lambda_c^+ \rightarrow \Lambda(1520)[\rightarrow pK^-]e^+\nu_e) = (0.23 \pm 0.12 \pm 0.02) \times 10^{-3}$ and $\mathcal{B}(\Lambda_c^+ \rightarrow \Lambda(1405)[\rightarrow pK^-]e^+\nu_e) = (0.42 \pm 0.19 \pm 0.04) \times 10^{-3}$, where the first uncertainties are statistical and the second are systematic. Due to limited data, the possible interference effects between $\Lambda_c^+ \rightarrow \Lambda(1520/1405)e^+\nu_e$ and $\Lambda_c^+ \rightarrow (pK^-)_{\text{NR}}e^+\nu_e$, as well as interference between $\Lambda(1520)$ and $\Lambda(1405)$ states, are ignored.

The DT technique means that the measured BFs are insensitive to any systematic uncertainties in the ST selection, as the effects of the ST selection criteria are canceled for both data and MC in the determination of the BFs. Sources of systematic uncertainty are, instead, related to the tracking and PID efficiencies of the e^+ (0.4% and 0.5%, respectively), p (1% and 1%), and K^- (1% and 1%), evaluated with control samples of radiative Bhabha scattering, $J/\psi \rightarrow p\bar{p}\pi^+\pi^-$ and $J/\psi \rightarrow K_S^0 K^\mp \pi^\pm$ events, respectively. The uncertainties arising from the fit are determined by using alternative line shapes to parametrize the signal and background contributions. For $\Lambda_c^+ \rightarrow pK^-e^+\nu_e$, the alternative fit uses the shape from MC simulation for the signal, with a constant to describe the combinatorial background for the U_{miss} distribution, which results in an uncertainty of 3.8%. For $\Lambda_c^+ \rightarrow \Lambda(1520)/\Lambda(1405)e^+\nu_e$, the masses and widths of the signal-function are varied by $\pm 1\sigma$, and a data-driven M_{pK^-} shape is used to describe the $\Lambda_c^+ \rightarrow pK^-\pi^+\pi^0$ background, which results in an uncertainty of 4.6/3.9%. The uncertainties due to the knowledge of R_B on the three BFs are estimated to be 3.0%, 1.4%, and 1.4% by varying the nominal value of R_B by ± 0.03 in the fits. The uncertainty of neglecting the possible decay $\Lambda_c^+ \rightarrow \Lambda(1520/1405)(\rightarrow pK^-)\mu^+\nu_\mu$ is evaluated to be 4.8/5.4%, by varying the description of $\Lambda_c^+ \rightarrow pK^-\mu^+\nu_\mu$ component with $\Lambda_c^+ \rightarrow (pK^-)_{\text{NR}}\mu^+\nu_\mu$ and $\Lambda_c^+ \rightarrow \Lambda(1520)/\Lambda(1405)\mu^+\nu_\mu$. The uncertainty arising from the MC model of $\Lambda_c^+ \rightarrow pK^-e^+\nu_e$ is assigned by varying the relative fraction of $\Lambda_c^+ \rightarrow (pK^-)_{\text{NR}}e^+\nu_e$ and $\Lambda_c^+ \rightarrow \Lambda(1520)/\Lambda(1405)e^+\nu_e$ by $\pm 1\sigma$ in the MC generation. In the case of $\Lambda_c^+ \rightarrow \Lambda(1520)/\Lambda(1405)e^+\nu_e$, a new MC model based on leading-order heavy-quark effective theory is introduced [10]. These alternative models lead to a relative difference of 3.7% and 2.7/3.6% in the efficiencies of $\Lambda_c^+ \rightarrow pK^-e^+\nu_e$ and $\Lambda_c^+ \rightarrow \Lambda(1520)/\Lambda(1405)e^+\nu_e$, respectively, which is assigned as the corresponding uncertainty. To account for neglecting possible interference effects in measuring the BF of $\Lambda_c^+ \rightarrow \Lambda(1520)/\Lambda(1405)e^+\nu_e$, an additional 6.1% uncertainty is assigned based on studies of

the inclusive $K\pi$ system in D SL decays [44,45]. In addition the uncertainties of the requirements on M_{BC} (2.1%), $M_{pK^-e^+}$ (3.1%), N_{ST} (1.0%) and the MC sample size (1.0%) are considered. Adding these contributions in quadrature gives a total systematic uncertainty of 7.8% for $\mathcal{B}(\Lambda_c^+ \rightarrow pK^-e^+\nu_e)$, 10.4% for $\mathcal{B}(\Lambda_c^+ \rightarrow \Lambda(1520)e^+\nu_e)$ and 10.7% for $\mathcal{B}(\Lambda_c^+ \rightarrow \Lambda(1405)e^+\nu_e)$. When considering each of these systematic contributions in turn, the minimum significance for $\Lambda_c^+ \rightarrow pK^-e^+\nu_e$ is determined to be 8.2σ . The minimum significance for $\Lambda_c^+ \rightarrow \Lambda(1520)e^+\nu_e$ and $\Lambda_c^+ \rightarrow \Lambda(1405)e^+\nu_e$ are determined to be 3.3σ and 3.2σ , respectively.

In summary, using 4.5 fb^{-1} of data collected at the center-of-mass energies from 4.600 GeV to 4.699 GeV, the SL decay $\Lambda_c^+ \rightarrow pK^-e^+\nu_e$ is observed with 8.2σ significance. We also find evidence for $\Lambda_c^+ \rightarrow \Lambda(1520)e^+\nu_e$ and $\Lambda_c^+ \rightarrow \Lambda(1405)e^+\nu_e$ with a significance of 3.3σ and 3.2σ , respectively. The measured BFs are $\mathcal{B}(\Lambda_c^+ \rightarrow pK^-e^+\nu_e) = (0.88 \pm 0.17 \pm 0.07) \times 10^{-3}$, $\mathcal{B}(\Lambda_c^+ \rightarrow \Lambda(1520)[\rightarrow pK^-]e^+\nu_e) = (0.23 \pm 0.12 \pm 0.02) \times 10^{-3}$ and $\mathcal{B}(\Lambda_c^+ \rightarrow \Lambda(1405)[\rightarrow pK^-]e^+\nu_e) = (0.42 \pm 0.19 \pm 0.04) \times 10^{-3}$. Taking into account that $\mathcal{B}(\Lambda(1520) \rightarrow N\bar{K}) = (45 \pm 1)\%$ [2], we measure $\mathcal{B}(\Lambda_c^+ \rightarrow \Lambda(1520)e^+\nu_e) = (1.02 \pm 0.52 \pm 0.11) \times 10^{-3}$. Comparisons of $\mathcal{B}(\Lambda_c^+ \rightarrow \Lambda(1520)/\Lambda(1405)e^+\nu_e)$ between the measurement and predicted values from theoretical models [8–10] as well as the LQCD [12,13] are shown in Table I. Our measured $\mathcal{B}(\Lambda_c^+ \rightarrow \Lambda(1520)e^+\nu_e)$ is consistent with these theoretical calculations within two standard deviations.

Combing the BF of $\Lambda_c^+ \rightarrow \Lambda(1520)e^+\nu_e$ measured in this work, τ_{Λ_c} and the q^2 -integrated rate predicted by LQCD [12,13], we determine $|V_{cs}| = 1.3 \pm 0.3_B \pm 0.1_{\text{LQCD}}$, which is in consistent with $|V_{cs}| = 0.97401(11)$ obtained assuming CKM unitarity [2] within one standard deviation. This is the first determination of $|V_{cs}|$ using data of baryonic SL decays in excited Λ state. Our results presented in this paper are valuable in extending the understanding of Λ_c^+ SL decays beyond the mode $\Lambda_c^+ \rightarrow \Lambda\ell^+\nu_\ell$, and represent a significant advance in knowledge since the discovery of the Λ_c^+ more than 40 years ago. The observation of $\Lambda_c^+ \rightarrow pK^-e^+\nu_e$ is that of the first SL Λ_c decay mode that does not contain a Λ baryon in the final state [8,11]. In addition, the observed pK^- invariant-mass spectrum in this work can provide new insights into the internal structure of excited Λ states as well as in the study of hyperon spectroscopy [9,14,17,46,47], complementary to the informations from the pentaquark

searches using $\Lambda_b \rightarrow pK^-J/\psi$ [43]. With the larger samples that BESIII expects to collect [48], an amplitude analysis of the pK^- mass spectrum will be performed to understand the internal structure of the contributing Λ^* states.

The BESIII Collaboration thanks the staff of BEPCII and the IHEP computing center for their strong support. APPENDIX: THE M_{BC} DISTRIBUTIONS FOR THE OTHER DATA SETS

Figures 4, 5, and 6 show the M_{BC} distributions obtained at $\sqrt{s} = 4.600, 4.612, 4.628, 4.641, 4.661, \text{ and } 4.699$ GeV, respectively. The ST yields for each of the ST modes collected at different energy points are given in Table II.

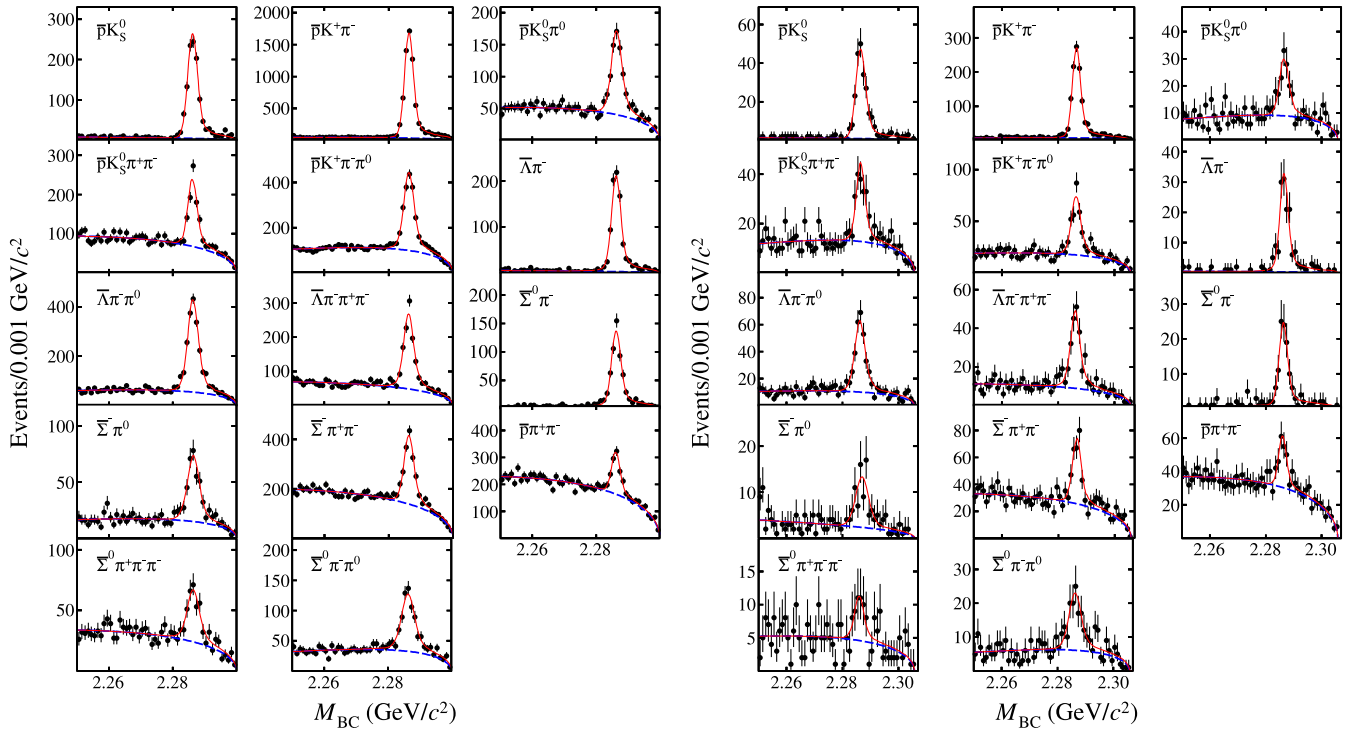

FIG. 4. Fits to M_{BC} distributions for different ST modes at (left) $\sqrt{s} = 4.600$ GeV and (right) $\sqrt{s} = 4.612$ GeV. The points with error bars are data, the (red) solid curves show the total fits and the (blue) dashed curves are the background shapes.

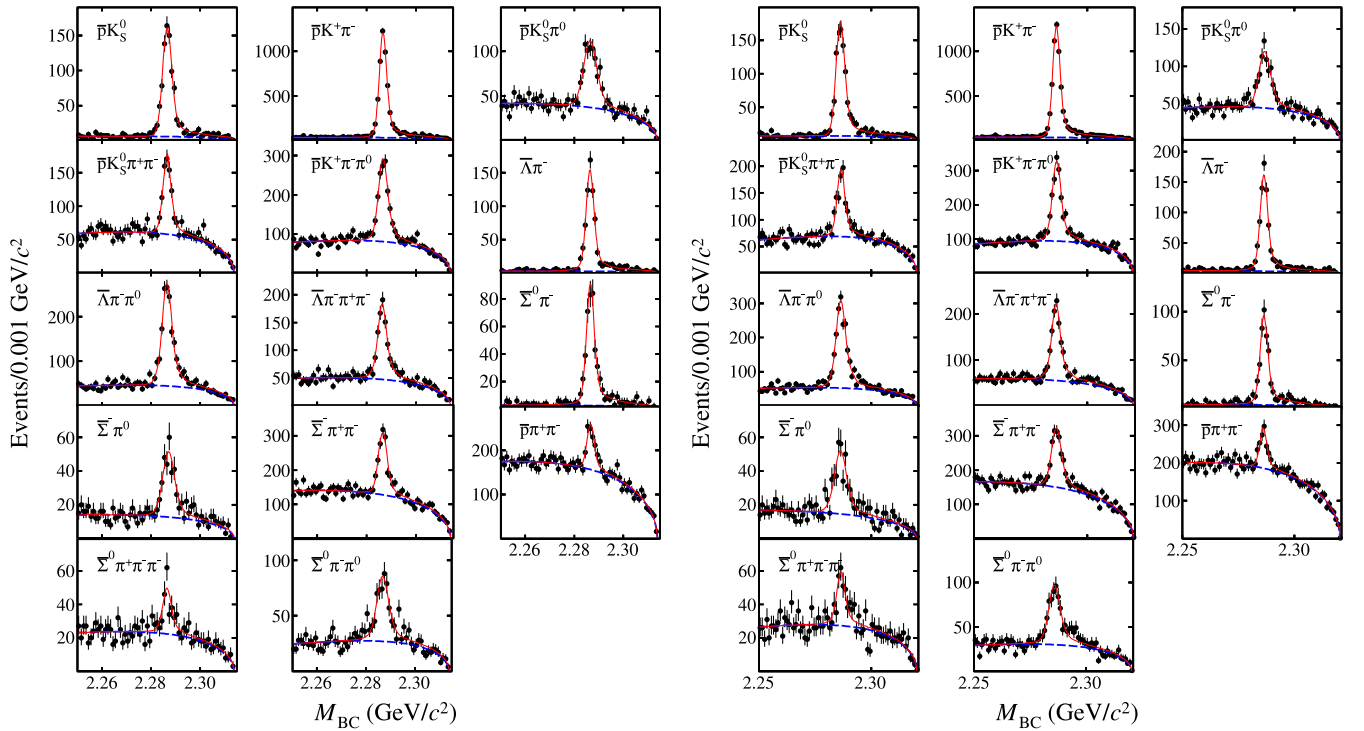

FIG. 5. Fits to M_{BC} distributions for different ST modes at (left) $\sqrt{s} = 4.628$ GeV and (right) $\sqrt{s} = 4.641$ GeV. The points with error bars are data, the (red) solid curves show the total fits and the (blue) dashed curves are the background shapes.

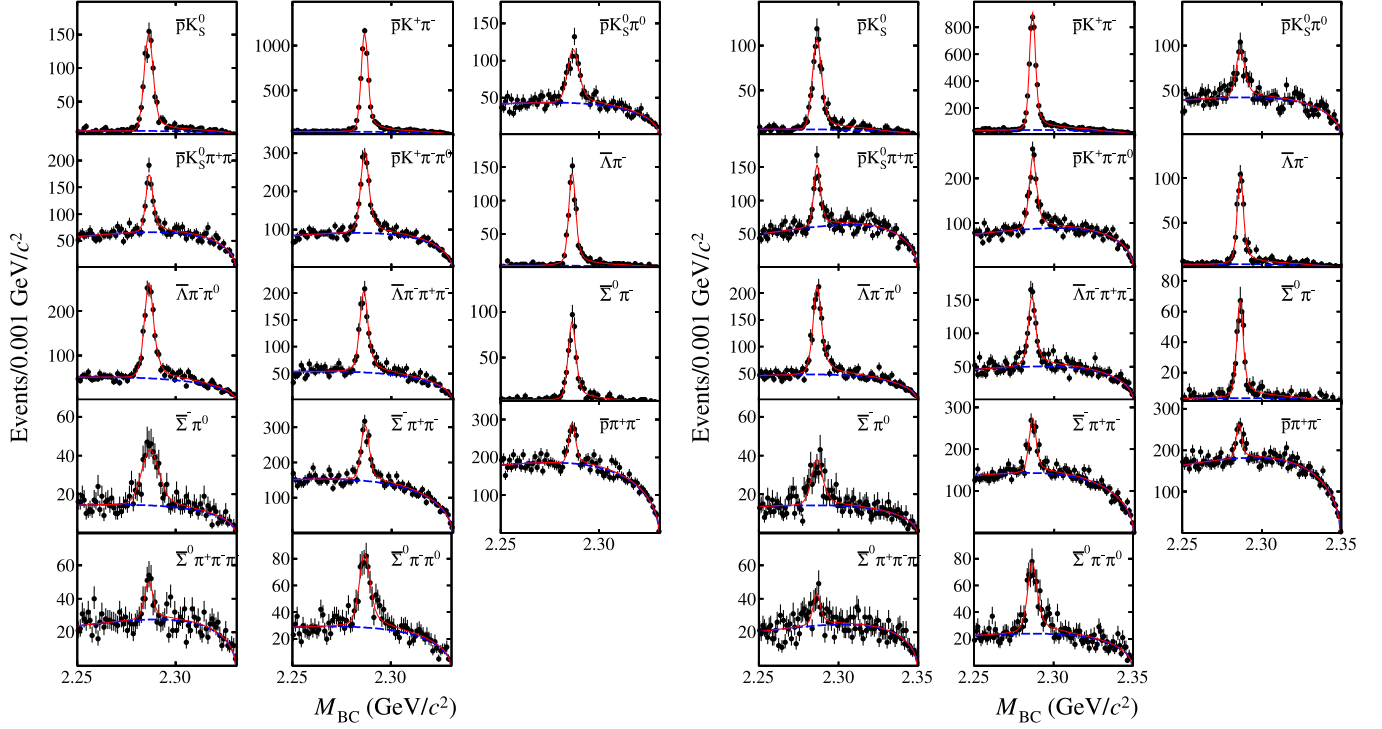

FIG. 6. Fits to M_{BC} distributions for different ST modes at (left) $\sqrt{s} = 4.661$ GeV and (right) $\sqrt{s} = 4.699$ GeV. The points with error bars are data, the (red) solid curves show the total fits and the (blue) dashed curves are the background shapes.

TABLE II. The ΔE requirements and the ST yields N_{ST} in each of the data sets.
