(Received 28 April 2020; accepted 1 June 2020; published 19 June 2020)

Using 2.93 fb^{-1} of e^+e^- collision data taken at a center-of-mass energy of 3.773 GeV with the BESIII detector, we report the first measurements of the absolute branching fractions of 14 hadronic $D^{0(+)}$ decays to exclusive final states with an η , e.g., $D^0 \rightarrow K^-\pi^+\eta$, $K_S^0\pi^0\eta$, $K^+K^-\eta$, $K_S^0K_S^0\eta$, $K^-\pi^+\pi^0\eta$, $K_S^0\pi^+\pi^-\eta$, $K_S^0\pi^0\pi^0\eta$, and $\pi^+\pi^-\pi^0\eta$; $D^+ \rightarrow K_S^0\pi^+\eta$, $K_S^0K^+\eta$, $K^-\pi^+\pi^+\eta$, $K_S^0\pi^+\pi^0\eta$, $\pi^+\pi^+\pi^-\eta$, and $\pi^+\pi^0\pi^0\eta$. Among these decays, the $D^0 \rightarrow K^-\pi^+\eta$ and $D^+ \rightarrow K_S^0\pi^+\eta$ decays have the largest branching fractions, which are $\mathcal{B}(D^0 \rightarrow K^-\pi^+\eta) = (1.853 \pm 0.025_{\text{stat}} \pm 0.031_{\text{syst}})\%$ and $\mathcal{B}(D^+ \rightarrow K_S^0\pi^+\eta) = (1.309 \pm 0.037_{\text{stat}} \pm 0.031_{\text{syst}})\%$, respectively. The charge-parity asymmetries for the six decays with highest event yields are determined, and no statistically significant charge-parity violation is found.

Hadronic D decays provide an ideal platform to explore strong and weak effects in decays of hadrons with charm or bottom quarks. Tests of lepton flavor universality (LFU) with semileptonic B decays are important to explore new physics beyond the standard model (SM). In recent years, the branching fraction (BF) ratios $\mathcal{R}_{\tau/\ell} =$

$\mathcal{B}_{B \rightarrow \bar{D}^{(*)}\tau^+\bar{\nu}_\tau} / \mathcal{B}_{B \rightarrow \bar{D}^{(*)}\ell^+\bar{\nu}_\ell}$ ($\ell = \mu, e$) measured by BABAR, Belle, and LHCb [1–8] were found to deviate from the SM prediction by 3.1σ [9]. It is argued in Ref. [10] that the exclusive hadronic $D^{0(+)}$ decays to η are key potential backgrounds in these tests. However, the known exclusive D^0 and D^+ decays to final states with an η meson only account for 44% and 16% of their corresponding inclusive rates [11], respectively. In particular, the BFs for the decays $D \rightarrow \bar{K}\pi\eta$, $K\bar{K}\eta$, $\bar{K}\pi\pi\eta$, and $\pi\pi\pi\eta$ (excluding narrow peaks K_S^0 , η , ω , η' , and ϕ in individual mass spectra) are poorly known, except for relative measurements of $D^0 \rightarrow K^-\pi^+\eta$ [12] and $D^0 \rightarrow K_S^0\pi^0\eta$ [13]. Measurements of the BFs of these decays are crucial to address the tensions found in

LFU tests with semileptonic B decays. Furthermore, combining the measured BF's with the corresponding amplitude analysis results gives important information on two-body hadronic D decays. This is essential for improving the understanding of quark U-spin [14–16] and SU(3)-flavor symmetry breaking effects, thereby benefiting theoretical predictions of $D^0\bar{D}^0$ mixing and charge-parity (CP) violation in D decays [16–23].

Studies of CP violation in the weak decays of hadrons are powerful tools for understanding physics within the SM and searches for physics beyond it. The CP violation in D decays is predicted to be up to a few times 10^{-3} [23–29] and has been recently observed to be $(1.54 \pm 0.29) \times 10^{-3}$ in $D^0 \rightarrow K^+K^-$ and $\pi^+\pi^-$ decays by LHCb [30]. However, knowledge of CP violation in D decays is still very limited. Searching for CP asymmetries in hadronic D decays, which have been much less explored than (semi-)leptonic decays, allows for a more comprehensive understanding of CP violation in the D sector.

This Letter reports the first measurements of the absolute BF's for the decays $D^0 \rightarrow K^-\pi^+\eta$, $K_S^0\pi^0\eta$, $K^+K^-\eta$, $K_S^0K_S^0\eta$, $K^-\pi^+\pi^0\eta$, $K_S^0\pi^+\pi^-\eta$, $K_S^0\pi^0\pi^0\eta$, $\pi^+\pi^-\pi^0\eta$, and $D^+ \rightarrow K_S^0\pi^+\eta$, $K_S^0K^+\eta$, $K^-\pi^+\pi^+\eta$, $K_S^0\pi^+\pi^0\eta$, $\pi^+\pi^+\pi^-\eta$, $\pi^+\pi^0\pi^0\eta$. Throughout this Letter, the charge conjugate processes are implied unless stated otherwise. In addition, the CP asymmetries are determined for the six decays with the highest yields. To avoid double-counting previously measured decays, the narrow peaks for the K_S^0 , η , ω , η' , and ϕ are removed from the mass spectra of the $\pi^{+(0)}\pi^{-(0)}$, $\pi^+\pi^-\pi^0$, $\pi^+\pi^-\pi^0$, $\pi^{+(0)}\pi^{-(0)}\eta$, and K^+K^- (or $\pi^+\pi^-\pi^0$) combinations, respectively.

The data sample was collected with the BESIII detector at a center-of-mass energy $\sqrt{s} = 3.773$ GeV and has an integrated luminosity of 2.93 fb^{-1} [31]. Details about the design and performance of the BESIII detector are given in Ref. [32]. The Monte Carlo (MC) simulated events are produced with a GEANT4-based [33] detector simulation software package. An inclusive MC sample, including $D^0\bar{D}^0$, D^+D^- and non- $D\bar{D}$ decays of the $\psi(3770)$, initial state radiation production of the $\psi(3686)$ and J/ψ , and the processes $e^+e^- \rightarrow q\bar{q}$ ($q = u, d, s$) and $e^+e^- \rightarrow (\gamma)\ell^+\ell^-$ ($\ell = e, \mu, \tau$), is produced to determine the detection efficiencies and to estimate any potential backgrounds. The production of the charmonium states is simulated by the MC generator KKMC [34]. The measured decay modes of the charmonium states are generated using EVTGEN [35] with BF's from the Particle Data Group [11], and the remaining unknown decay modes are generated by LUNDCHARM [36].

The BF's of the hadronic D (D^0 or D^+) decays are measured via the reaction chain $e^+e^- \rightarrow \psi(3770) \rightarrow D\bar{D}$. If a \bar{D} meson is fully reconstructed, it is called a single-tag (ST) \bar{D} meson. The ST D^- mesons are reconstructed via the decays $D^- \rightarrow K^+\pi^-\pi^-$, $K_S^0\pi^-$, $K^+\pi^-\pi^-\pi^0$, $K_S^0\pi^-\pi^0$, $K_S^0\pi^+\pi^-\pi^-$, and $K^+K^-\pi^-$, while the ST \bar{D}^0 mesons are

reconstructed using the decays $\bar{D}^0 \rightarrow K^+\pi^-$, $K^+\pi^-\pi^0$, and $K^+\pi^-\pi^-\pi^+$. If a signal decay is fully reconstructed in the system recoiling against an ST \bar{D} meson, the candidate event is called a double-tag (DT) event. The BF of the signal decay is given by

$$\mathcal{B}_{\text{sig}} = N_{\text{DT}} / (N_{\text{ST}} \cdot \epsilon_{\text{sig}}), \quad (1)$$

where $N_{\text{ST}} = \sum_i N_{\text{ST}}^i$ and N_{DT} are the total ST and DT yields in data, respectively, and $\epsilon_{\text{sig}} = \sum_i (N_{\text{ST}}^i \cdot \epsilon_{\text{DT}}^i / \epsilon_{\text{ST}}^i) / N_{\text{ST}}$ is the effective efficiency for detecting the signal decay, averaged over tag mode i , where ϵ_{ST} and ϵ_{DT} are the efficiencies for detecting ST and DT candidates, respectively.

We use the same selection criteria for K^\pm , π^\pm , K_S^0 , γ , and π^0 as were used in Refs. [37–43]. Candidates for η are reconstructed from $\gamma\gamma$ pairs with invariant mass within $(0.515, 0.570) \text{ GeV}/c^2$. To improve resolution, a one-constraint kinematic fit is imposed on each $\gamma\gamma$ pair to constrain their invariant mass at η nominal mass [11]. For $\bar{D}^0 \rightarrow K^+\pi^-\pi^-\pi^+$ tags, the $\bar{D}^0 \rightarrow K_S^0K^\pm\pi^\mp$ decays are rejected if the mass of any $\pi^+\pi^-$ pair falls in the range $(0.478, 0.518) \text{ GeV}/c^2$.

Tagging \bar{D} (signal D) mesons are identified by two variables, the energy difference $\Delta E_{\text{tag}(\text{sig})} \equiv E_{\text{tag}(\text{sig})} - E_b$ and the beam-constrained mass $M_{\text{BC}}^{\text{tag}(\text{sig})} \equiv \sqrt{E_b^2 - |\vec{p}_{\text{tag}(\text{sig})}|^2}$, where tag (sig) represents the tagging \bar{D} (signal D), E_b the beam energy, and $\vec{p}_{\text{tag}(\text{sig})}$ and $E_{\text{tag}(\text{sig})}$ the momentum and energy of the \bar{D} (D) candidate in the e^+e^- rest frame. For each tag (signal) mode, if there are multiple combinations, only the one with the minimum $|\Delta E_{\text{tag}(\text{sig})}|$ is kept for further analysis. The \bar{D} tags are required to satisfy $\Delta E_{\text{tag}} \in (-55, 40) \text{ MeV}$ for the modes containing π^0 in the final states and $\Delta E_{\text{tag}} \in (-25, 25) \text{ MeV}$ for the other modes. The yields of ST \bar{D} mesons are obtained from binned maximum likelihood fits to the $M_{\text{BC}}^{\text{tag}}$ distributions of the accepted ST candidates following Refs. [37–41]. The total ST D^- yield is $N_{\text{STD}^-} = 1558159 \pm 2113_{\text{stat}}$. The total ST \bar{D}^0 yield is $N_{\text{ST}\bar{D}^0} = 2327839 \pm 1860_{\text{stat}}$ for self-conjugate signal D^0 decays. For the flavor specific signal decays $D^0 \rightarrow K^-\pi^+\eta$ and $K^-\pi^+\pi^0\eta$, we remove doubly Cabibbo suppressed decays from the ST selection, giving $N_{\text{ST}\bar{D}^0} = 2321430 \pm 1860_{\text{stat}}$ for these decays.

For the signal D decays recoiling against the \bar{D} tags, tracks are selected from the residual tracks that have not been used for the tag reconstruction. The signal D decays are selected by using the ΔE_{sig} requirements as listed in Table I. For the $\pi^+\pi^-[\pi^0\pi^0]$, $\pi^+\pi^-\pi^0$, $\pi^+\pi^-\pi^0$, $\pi^+(0)\pi^{-(0)}\eta$, and K^+K^- combinations, the K_S^0 , η , ω , η' , and ϕ contributions are rejected by requiring their invariant masses to be outside $(0.468, 0.528) \text{ GeV}/c^2$ [$(0.438, 0.538) \text{ GeV}/c^2$], $(0.498, 0.578) \text{ GeV}/c^2$, $(0.732, 0.832) \text{ GeV}/c^2$, $(0.908, 1.008) \text{ GeV}/c^2$, and $(0.990, 1.390) \text{ GeV}/c^2$, respectively.

TABLE I. Requirements on ΔE_{sig} , net DT yields in data (N_{DT}), detection efficiencies (ϵ_{sig} , including the BFs of K_S^0 , η , and π^0 as well as correction factors described later), and the obtained BFs (\mathcal{B}_{sig}). Numbers in the first and second brackets are last two effective digits of statistical and systematic uncertainties, respectively, for \mathcal{B}_{sig} . The uncertainty is statistical only for N_{DT} . The efficiency of $D^0 \rightarrow K^+ K^- \eta$ is significantly lower than that of $D^0 \rightarrow K^- \pi^+ \eta$ because of lower selection efficiencies of K^- , K^+ , and η due to smaller PHSP as well as ϕ veto in $K^+ K^-$ mass spectrum.

Decay	ΔE_{sig} (MeV)	N_{DT}	ϵ_{sig} (%)	\mathcal{B}_{sig} ($\times 10^{-4}$)
$D^0 \rightarrow K^- \pi^+ \eta$	(-37, 36)	6116.2 ± 81.8	14.22	185.3(25)(31)
$D^0 \rightarrow K_S^0 \pi^0 \eta$	(-57, 45)	1092.7 ± 35.2	4.66	100.6(34)(30)
$D^0 \rightarrow K^+ K^- \eta$	(-27, 27)	13.1 ± 4.0	9.53	0.59(18)(05)
$D^0 \rightarrow K_S^0 K_S^0 \eta$	(-29, 28)	7.3 ± 3.2	2.36	1.33(59)(18)
$D^0 \rightarrow K^- \pi^+ \pi^0 \eta$	(-44, 36)	576.5 ± 28.8	5.53	44.9(22)(15)
$D^0 \rightarrow K_S^0 \pi^+ \pi^- \eta$	(-33, 32)	248.2 ± 18.0	3.80	28.0(19)(10)
$D^0 \rightarrow K_S^0 \pi^0 \pi^0 \eta$	(-56, 41)	64.7 ± 9.2	1.58	17.6(23)(13)
$D^0 \rightarrow \pi^+ \pi^- \pi^0 \eta$	(-57, 45)	508.6 ± 26.0	6.76	32.3(17)(14)
$D^+ \rightarrow K_S^0 \pi^+ \eta$	(-36, 36)	1328.2 ± 37.8	6.51	130.9(37)(31)
$D^+ \rightarrow K_S^0 K^+ \eta$	(-27, 27)	13.6 ± 3.9	4.72	1.85(52)(08)
$D^+ \rightarrow K^- \pi^+ \pi^+ \eta$	(-33, 33)	188.0 ± 15.3	8.94	13.5(11)(04)
$D^+ \rightarrow K_S^0 \pi^+ \pi^0 \eta$	(-49, 41)	48.7 ± 9.7	2.57	12.2(24)(06)
$D^+ \rightarrow \pi^+ \pi^+ \pi^- \eta$	(-40, 38)	514.6 ± 25.7	9.67	34.1(17)(10)
$D^+ \rightarrow \pi^+ \pi^0 \pi^0 \eta$	(-70, 49)	192.5 ± 17.1	3.86	32.0(28)(17)

These correspond to at least five times the fitted mass resolution away from individual nominal mass. For $D^0 \rightarrow K_S^0 \pi^{+(0)} \pi^{-(0)} \eta$ [$\pi^+ \pi^- \pi^0 \eta$] decays, no aforementioned mass requirements of the $K_S^0[\phi]$ are imposed on the $\pi^{+(0)} \pi^{-(0)}$ [$\pi^+ \pi^- \pi^0$] combinations, due to the small BFs and the limited phase space (PHSP) of the background channels $D^0 \rightarrow K_S^0 K_S^0 \eta$ [$\phi \eta$]. The opening angle between signal D and tagging \bar{D} is required to be greater than 160° , with a loss of (2–6)% of the signal, to suppress misformed $D\bar{D}$ candidates. For $D \rightarrow \bar{K} \pi \pi^0 \eta$, the peaking backgrounds (PBKG) of $D \rightarrow \bar{K} \pi \pi^0 \pi^0$ are rejected if any $\bar{K} \pi \pi^0 \pi^0$ combinations satisfying $\Delta E_{\bar{K} \pi \pi^0 \pi^0} \in (-0.05, 0.05)$ GeV and $M_{\text{BC}}^{\bar{K} \pi \pi^0 \pi^0} \in (1.83, 1.89)$ GeV/ c^2 can be found in the same candidate events. The combination of these requirements rejects more than 75% of the background and keeps (93–97)% of the signal.

To determine the DT yields in the data ($N_{\text{DT}}^{\text{fit}}$), a two-dimensional (2D) unbinned maximum likelihood fit is performed on the $M_{\text{BC}}^{\text{tag}}$ vs $M_{\text{BC}}^{\text{sig}}$ distribution of the accepted DT candidates (see Fig. 1 of the Supplemental Material [44] for an example). Signal events concentrate around $M_{\text{BC}}^{\text{tag}} = M_{\text{BC}}^{\text{sig}} = M_D$, where M_D is the nominal D mass [11]. Background events are divided into three categories. The first one (named BKG I) is from events with correctly reconstructed D (\bar{D}) and incorrectly reconstructed \bar{D} (D). They are spread along the lines around $M_{\text{BC}}^{\text{tag}}$ or $M_{\text{BC}}^{\text{sig}} = M_D$. The second one (named BKG II) is from events smeared along the diagonal, which are mainly from the $e^+ e^- \rightarrow q\bar{q}$ processes. The third one (named BKG III) comes from events with uncorrelated and incorrectly reconstructed D and \bar{D} .

In the 2D fit, the probability density functions (PDFs) of the backgrounds are constructed as (i) BKG I: $b(x) \cdot c_y(y; E_b, \xi_y, \frac{1}{2}) + b(y) \cdot c_x(x; E_b, \xi_x, \frac{1}{2})$, (ii) BKG II:

$c_z(z; \sqrt{2}E_b, \xi_z, \frac{1}{2}) \cdot g(k; 0, \sigma_k)$, and (iii) BKG III: $c_x(x; E_b, \xi_x, \frac{1}{2}) \cdot c_y(y; E_b, \xi_y, \frac{1}{2})$. Here, $x = M_{\text{BC}}^{\text{sig}}$, $y = M_{\text{BC}}^{\text{tag}}$, $z = (x + y)/\sqrt{2}$, and $k = (x - y)/\sqrt{2}$. The PDFs for signal, $a(x, y)$, $b(x)$, and $b(y)$, are described by the corresponding MC-simulated shapes. $c_f(f; E_b, \xi_f, \frac{1}{2})$ is an ARGUS function [45] defined as $A_f \cdot f \cdot [1 - (f^2/E_b^2)]^{1/2} \cdot e^{\xi_f(1-f^2/E_b^2)}$, where f denotes x , y , or z ; E_b is fixed at 1.8865 GeV/ c^2 ; A_f is a normalization factor; and ξ_f is a fit parameter. $g(k; 0, \sigma_k)$ is a Gaussian function with mean of zero and standard deviation $\sigma_k = \sigma_0 \cdot (\sqrt{2}E_b - z)^p$, where σ_0 and p are two free parameters. In addition to these backgrounds, for the decays $D^0 \rightarrow K_S^0 \pi^{+(0)} \pi^{-(0)} \eta$, $\pi^+ \pi^- \pi^0 \eta$, $K^- \pi^+ \pi^0 \eta$, $K_S^0 \pi^0 \pi^0 \eta$, and $D^+ \rightarrow K_S^0 \pi^+ \pi^0 \eta$, the yields and shapes of the PBKG components are fixed based on MC simulations. All other parameters are left free.

Combinatorial $\pi^+ \pi^-$ pairs can also satisfy the K_S^0 selection criteria and form peaking backgrounds around the D mass in the $M_{\text{BC}}^{\text{sig}}$ distribution. This kind of peaking background is estimated by the data events in the K_S^0 sideband region. For $D^0 \rightarrow K_S^0 \pi^0 \eta$, $K_S^0 \pi^+ \pi^- \eta$, $K_S^0 \pi^0 \pi^0 \eta$, and $D^+ \rightarrow K_S^0 \pi^+ \eta$, $K_S^0 K^+ \eta$, $K_S^0 \pi^+ \pi^0 \eta$, one-dimensional (1D) signal and sideband regions are defined as $M_{\pi^+ \pi^-} \in (0.486, 0.510)$ GeV/ c^2 and $M_{\pi^+ \pi^-} \in (0.454, 0.478) \cup (0.518, 0.542)$ GeV/ c^2 , respectively. For $D^0 \rightarrow K_S^0 K_S^0 \eta$, 2D signal and sideband regions are defined. The 2D sideband 1 (2) regions are defined as the boxes in which one (two) of the two $\pi^+ \pi^-$ combinations lie in the K_S^0 sideband regions and the rest are located in the K_S^0 signal regions. See Fig. 2 of the Supplemental Material [44] as an example.

For the decays involving K_S^0 , the net DT yields are obtained by $N_{\text{DT}} = N_{\text{DT}}^{\text{fit}} - \frac{1}{2}(N_{\text{sid-1}}^{\text{fit}} - N_{\text{sid-2}}^{\text{fit}}) - \frac{1}{4}N_{\text{sid-2}}^{\text{fit}} = N_{\text{DT}}^{\text{fit}} - \frac{1}{2}N_{\text{sid-1}}^{\text{fit}} + \frac{1}{4}N_{\text{sid-2}}^{\text{fit}}$, where $N_{\text{DT}}^{\text{fit}}$ and $N_{\text{sid-}i}^{\text{fit}}$ are the fitted DT yields in the K_S^0 signal region and sideband i region, respectively. This relation has been verified based on MC simulation. For the other decays, the net DT yields are $N_{\text{DT}}^{\text{fit}}$.

For each signal decay mode, the statistical significance is calculated by $\sqrt{-2\ln(\mathcal{L}_0/\mathcal{L}_{\text{max}})}$, where \mathcal{L}_{max} and \mathcal{L}_0 are the maximum likelihoods with and without the signal component in the fits, respectively. The effect of combinatorial $\pi^+\pi^-$ backgrounds in the K_S^0 signal regions has been considered for the decays involving K_S^0 . The statistical significances of the four decays with lowest yields, $D^0 \rightarrow K^+K^-\eta$, $K_S^0K_S^0\eta$, $D^+ \rightarrow K_S^0K^+\eta$, and $K_S^0\pi^+\pi^0\eta$, are 5.5σ , 2.8σ , 5.7σ , and 8.4σ , respectively; those for the other decays are all greater than 10σ .

To determine the signal efficiencies (ϵ_{sig}), the $D \rightarrow \bar{K}\pi\eta$ decays are simulated with a modified data-driven generator BODY3 [35], which was developed to simulate different intermediate states in data for a given three-body final state. The Dalitz plot of $M_{\bar{K}\pi}^2$ vs $M_{\pi\eta}^2$ found in data, corrected for backgrounds and efficiencies, is taken as input for the BODY3 generator. The efficiencies across the kinematic space are obtained with MC samples generated with the PHSP generator. Intermediate states in the $D^0 \rightarrow K^+K^-\eta$, $K_S^0K_S^0\eta$, $K_S^0\pi^+\pi^0\eta$, and $D^+ \rightarrow K_S^0K^+\eta$, $K_S^0\pi^+\pi^0\eta$ decays cannot be determined due to limited statistics; these decays are therefore simulated with the PHSP generator. Each of the other decays is simulated with a mixed signal MC sample. Here, the decays generated with PHSP generator and the decays containing $K^*(892)$, $\rho(770)$, and $a_0(980)$ intermediate states are mixed with fractions obtained by examining the corresponding invariant mass spectra. The

data distributions for momenta and $\cos\theta$ (where θ is the polar angle in the e^+e^- rest frame) of the daughter particles, and the invariant masses of each of the two- and three-body particle combinations, agree with the MC simulations. The differences between the DT efficiencies obtained with the BODY3 and PHSP generators will be assigned as a systematic uncertainty.

The values for N_{DT} , ϵ_{sig} , and the BFs of the signal decays are summarized in Table I. The BF upper limit for $D^0 \rightarrow K_S^0K_S^0\eta$ at 90% confidence level is determined to be $< 2.4 \times 10^{-4}$ using the Bayesian approach after incorporating the systematic uncertainty [46].

The systematic uncertainties arise from the sources discussed below and are estimated relative to the measured BFs. The uncertainties in the total ST yields come from the $M_{\text{BC}}^{\text{tag}}$ fits to the ST \bar{D} candidates, which were determined as 0.5% for both neutral and charged \bar{D} [37–39]. The systematic uncertainties of the tracking efficiencies are found to be (0.2–0.5)% per K^\pm or π^\pm , while those for PID efficiencies are taken as (0.2–0.3)% per K^\pm or π^\pm , by using DT $D\bar{D}$ hadronic events. The systematic uncertainty in K_S^0 reconstruction is estimated to be 1.6% per K_S^0 by using the $J/\psi \rightarrow K^*(892)^\mp K^\pm$ and $J/\psi \rightarrow \phi K_S^0 K^\pm \pi^\mp$ candidates [47]. The systematic uncertainty of the π^0 reconstruction is assigned as (0.7–0.8)% per π^0 from studies of DT $D\bar{D}$ hadronic decay samples of $D^0 \rightarrow K^-\pi^+$, $K^-\pi^+\pi^+\pi^-$ vs $\bar{D}^0 \rightarrow K^+\pi^-\pi^0$, $K_S^0\pi^0$ [37,38]. The systematic uncertainty for η reconstruction is taken to be the same as that for π^0 . The uncertainties of the quoted BFs of $K_S^0 \rightarrow \pi^+\pi^-$, $\eta \rightarrow \gamma\gamma$, and $\pi^0 \rightarrow \gamma\gamma$ decays are 0.07%, 0.5%, and 0.03% [11], respectively.

To estimate the systematic uncertainty in 2D fit, we repeat the fits by varying the signal shape, the endpoint of the ARGUS function ($\pm 0.2 \text{ MeV}/c^2$), the fixed PBKG

FIG. 1. Projections on $M_{\text{BC}}^{\text{tag}}$ and $M_{\text{BC}}^{\text{sig}}$ of the 2D fits to the DT candidate events. Data are shown as dots with error bars. Blue solid, red dotted, blue dot-dashed, black dot-long-dashed, green long-dashed, and pink dashed curves denote the overall fit results, signal, BKG I, BKG II, BKG III, and PBKG components (see text), respectively.

yield ($\pm 1\sigma$ of the quoted BF). The systematic uncertainty of the $D\bar{D}$ opening angle requirement is assigned as 0.4% by using the DT events of $D^0 \rightarrow K^-\pi^+\pi^0$. The systematic uncertainty due to the ΔE_{sig} requirement is assigned to be 0.3%, which is the largest efficiency difference with and without smearing the data-MC Gaussian resolution of ΔE_{sig} for signal MC events. Here, the parameters of the Gaussian are obtained by using the DT samples of $D^0 \rightarrow K_S^0\pi^0$, $K^-\pi^+\pi^0$, $K^-\pi^+\pi^0\pi^0$, and $D^+ \rightarrow K^-\pi^+\pi^+\pi^0$. The systematic uncertainties due to the choice of the K_S^0 sideband and the $K_S^0/\omega/\eta^{(\prime)}/\phi$ rejection windows are assigned by examining the changes of the BFs when varying the nominal K_S^0 sideband and rejection windows by ± 5 MeV/ c^2 . The uncertainties due to limited MC statistics (0.3–1.1)% are considered as a source of systematic uncertainty.

The systematic uncertainties in MC modeling are categorized into three cases. For the $D \rightarrow \bar{K}\pi\eta$ decays, the differences between the DT efficiencies obtained with the BODY3 and PHSP generators are assigned as the uncertainties. For the decays whose efficiencies are estimated with the PHSP generator, the uncertainties are assigned by referring to the largest change of the efficiencies among $D^0 \rightarrow K^-\pi^+\eta$, $K_S^0\pi^0\eta$, and $D^+ \rightarrow K_S^0\pi^+\eta$. For the decays whose efficiencies are estimated with the mixed signal MC events, the systematic uncertainties are assigned as the change of the DT efficiency after removing the smallest component.

The $D^0\bar{D}^0$ pairs are produced coherently at the $\psi(3770)$. For the decays $D^0 \rightarrow K_S^0\pi^0\eta$, $K^+K^-\eta$, $K_S^0K_S^0\eta$, $K_S^0\pi^+\pi^-\eta$, $K_S^0\pi^0\pi^0\eta$, and $\pi^+\pi^-\pi^0\eta$, the measured BFs are affected by various CP components due to quantum-correlation (QC) effects. The fractions of $CP+$ components in these decays are examined by the $CP+$ tag of $D^0 \rightarrow K^+K^-$ and $CP-$ tag of $D^0 \rightarrow K_S^0\pi^0$, with the same method described in Ref. [48], and the necessary parameters are taken from Refs. [49–51]. The obtained impact of QC effects on the BFs (f_{QC}) is shown in Table I of the Supplemental Material [44]. The signal efficiencies are corrected by the corresponding f_{QC} factors; the residual statistical errors of f_{QC} are assigned as the systematic uncertainties.

For each signal decay, the total systematic uncertainty is obtained by adding the above effects in quadrature. The systematic uncertainties for the various signal decays are given in Table II of the Supplemental Material [44] and the individual absolute systematic errors are summarized in Table I of text.

For the six decay modes with the highest yields, the BFs of D and \bar{D} decays, $\mathcal{B}_{\text{sig}}^+$ and $\mathcal{B}_{\text{sig}}^-$, are measured separately. Their asymmetry is determined by $\mathcal{A}_{CP}^{\text{sig}} = (\mathcal{B}_{\text{sig}}^+ - \mathcal{B}_{\text{sig}}^-) / (\mathcal{B}_{\text{sig}}^+ + \mathcal{B}_{\text{sig}}^-)$. The obtained BFs and asymmetries are summarized in Table II. We find no statistically significant CP violation. Several systematic uncertainties cancel in the asymmetry: the tracking and PID of $\pi^+\pi^-/K^+K^-$ pair, K_S^0

TABLE II. Charge-conjugated BFs ($\mathcal{B}_{\text{sig}}^+$ and $\mathcal{B}_{\text{sig}}^-$), and their asymmetries ($\mathcal{A}_{CP}^{\text{sig}}$). The first and second uncertainties are statistical and systematic, respectively, for $\mathcal{A}_{CP}^{\text{sig}}$; uncertainties for $\mathcal{B}_{\text{sig}}^+$ and $\mathcal{B}_{\text{sig}}^-$ are only statistical.

Decay	$\mathcal{B}_{\text{sig}}^+ (\times 10^{-4})$	$\mathcal{B}_{\text{sig}}^- (\times 10^{-4})$	$\mathcal{A}_{CP}^{\text{sig}} (\%)$
$D^0 \rightarrow K^-\pi^+\eta$	182.1 ± 3.5	189.1 ± 3.6	$-1.9 \pm 1.3 \pm 1.0$
$D^0 \rightarrow K_S^0\pi^0\eta$	98.4 ± 4.8	106.3 ± 5.1	$-3.9 \pm 3.2 \pm 0.8$
$D^0 \rightarrow K^-\pi^+\pi^0\eta$	41.7 ± 2.7	48.8 ± 3.2	$-7.9 \pm 4.8 \pm 2.5$
$D^0 \rightarrow \pi^+\pi^-\pi^0\eta$	29.8 ± 2.2	33.3 ± 2.5	$-5.5 \pm 5.2 \pm 2.4$
$D^+ \rightarrow K_S^0\pi^+\eta$	129.9 ± 5.3	132.3 ± 5.4	$-0.9 \pm 2.9 \pm 1.0$
$D^+ \rightarrow \pi^+\pi^+\pi^-\eta$	35.4 ± 2.4	33.7 ± 2.4	$+2.5 \pm 5.0 \pm 1.6$

reconstruction, π^0/η reconstruction, quoted BFs, K_S^0 sideband choice, $K_S^0/\omega/\eta^{(\prime)}/\phi$ rejection windows, MC modeling, and strong phase of D^0 decays. The other systematic uncertainties are estimated separately as above.

In summary, with 2.93 fb^{-1} of data taken at $\sqrt{s} = 3.773 \text{ GeV}$ with the BESIII detector, we report the first measurements of the absolute BFs of 14 exclusive $D^{0(+)}$ decays to η . Summing over the BFs measured in this work, and using the world averaged values of other known decays [11], the total BFs of all the exclusive D^0 and D^+ decays to η are determined to be $(8.62 \pm 0.35)\%$ and $(4.68 \pm 0.18)\%$, respectively. Here, the systematic uncertainties of N_{ST} , K^\pm/π^\pm tracking and PID, K_S^0 and η reconstruction, and the quoted BFs are correlated. They are consistent with the corresponding inclusive rates $(9.5 \pm 0.9)\%$ and $(6.5 \pm 0.7)\%$ within 0.9σ and 2.5σ , respectively, leaving little room for other exclusive decays involving η . The reported BFs provide key inputs for accurate background estimations in LFU tests with semileptonic B decays, which are crucial to explore possible new physics beyond the SM. The obtained $\mathcal{B}(D^0 \rightarrow K^-\pi^+\eta)$ agrees with the recent Belle result [11,12] within 1.3σ , with precision improved twofold. Our $\mathcal{B}(D^0 \rightarrow K_S^0\pi^0\eta)$ is greater than CLEO's result [11,13] by 3.7σ . Combining the measured $\mathcal{B}(D^0 \rightarrow K_S^0\pi^0\eta)$ with the fit fraction $\mathcal{B}(D^0 \rightarrow \bar{K}^*(892)^0\eta, \bar{K}^*(892)^0 \rightarrow K_S^0\pi^0) / \mathcal{B}(D^0 \rightarrow K_S^0\pi^0\eta)$ from CLEO [13], we find $\mathcal{B}(D^0 \rightarrow \bar{K}^*(892)^0\eta) = (1.77 \pm 0.44)\%$, where the uncertainty is dominated by the fit fraction. This deviates from various theoretical calculations [18,19,23] by 1.9 – 2.9σ . Future amplitude analyses of these decays at BESIII [52] and Belle II [53] will open a window to extract more two-body hadronic D decays, which are important to understand quark U-spin and SU(3)-flavor symmetry breaking effects and will be beneficial for the predictions of $D^0\bar{D}^0$ mixing and CP violation in D decays [18,19,23]. In addition, we determine the asymmetries of the charge-conjugated BFs for the six D decays with highest yields, and we find no statistically significant CP violation.

BESIII Collaboration thanks the staff of BEPCII and the IHEP computing center for their strong support. This work
