Insecta Mundi is a journal primarily devoted to insect systematics, but articles can be published on any non-marine arthropod. Topics considered for publication include systematics, taxonomy, nomenclature, checklists, faunal works, and natural history. **Insecta Mundi** will not consider works in the applied sciences (i.e. medical entomology, pest control research, etc.), and no longer publishes book reviews or editorials. **Insecta Mundi** publishes original research or discoveries in an inexpensive and timely manner, distributing them free via open access on the internet on the date of publication.

Insecta Mundi is referenced or abstracted by several sources including the Zoological Record, CAB Abstracts, etc. **Insecta Mundi** is published irregularly throughout the year, with completed manuscripts assigned an individual number. Manuscripts must be peer reviewed prior to submission, after which they are reviewed by the editorial board to ensure quality. One author of each submitted manuscript must be a current member of the Center for Systematic Entomology.

Abstract. A biodiversity inventory of the Lepidoptera of Pico Bonito National Park and vicinity, in the Department of Atlantida of northern Honduras, was initiated in 2009 to obtain baseline data. We present a revised checklist of Honduran butterfly species (updated from the initial 1967 lists), as well as the first comprehensive list of Honduran moths. Our updated list includes 550 species of Papilioidea, 311 Hesperioidea, and 1,441 moth species.

Keywords. Mesoamerica, Neotropical, Central America, biodiversity, faunal composition, Lepidoptera, Honduras.

Introduction

A comprehensive inventory of the Lepidoptera of Honduras has been initiated by the McGuire Center for Lepidoptera and Biodiversity, Florida Museum of Natural History, in collaboration with the Centro Zamorano de Biodiversidad, Escuela Agrícola Panamericana–Zamorano, The Lodge at Pico Bonito, and the Centro Universitario Regional del Litoral Atlántico. Together with the support of taxonomic specialists at various institutions, students, research associates, and ecotourism citizen-scientist participants, we seek to expand the knowledge and appreciation of the faunal diversity and natural history of Honduras. In addition, our objectives are to provide research and reference material for current and future studies on the phylogeny, systematics, and zoogeography of Lepidoptera. To date, our survey efforts have concentrated on the northern coast, while at the same time assembling data from literature records and museum specimens from areas throughout Honduras. The present

publication summarizes the results of the first two years of our surveys (2009-2010) in the form of an annotated list, and gives an introduction to the biodiversity, biogeography, and climate of the region. In addition, we provide a brief description of the principal study area and a general review of the history of previous biodiversity studies on Lepidoptera of Mesoamerica.

Biodiversity, Historical Geology, and Biogeography

Mesoamerica is a biodiversity hotspot that includes all tropical and subtropical ecosystems from eastern Panama north and west through Costa Rica, Nicaragua, Honduras, El Salvador, Belize, and Guatemala, in addition to portions of southern and coastal Mexico. Approximately 40% of the Mesoamerican forests are theoretically still present today but they are often highly fragmented. Although the Mesoamerican corridor does not have the breadth or the high elevations of the Andes, there are numerous metamorphic mountain chains throughout the region with peaks reaching 4000 m, in addition to a series of active volcanoes (Mittermeier et al. 1999). The intervening lowlands and valleys throughout these cordilleras have acted as corridors for animal and human migrations and dispersal over millions of years. Historical geological evidence suggests a rather wide separation of the two continents from the Cretaceous through the Oligocene and into the late Miocene (Raven and Axelrod 1974; Gose 1985; Pindell and Dewey 1982; Smith 1985; Smith and Bredin 1977; Miller and Miller 2001). It has been suggested that once the contiguous land connection was complete during the Pliocene (3 mybp) (Donnelly 1992; Iturrealde-Vinent and MacPhee 1999) to 5.7 mybp (Webb 1978, 1985, 1991, 2006), an extensive faunal exchange began. The species that inhabit these areas today are relicts of the fauna and flora from both North and South America. Thus, the Mesoamerican biodiversity hotspot exhibits a unique geological and evolutionary history with a patchwork of habitats supporting some of the highest levels of biodiversity and endemism on earth.

Climate and Habitats

The Caribbean lowlands of Honduras are among the wettest sections of Central America, with 2,500-6,500 mm of annual rainfall (occurring throughout the year), consistently warm temperatures, and high humidity. Alternatively, the Pacific lowlands and interior of Honduras have pronounced wet and dry seasons, with rain shadow effects associated with various mountain ranges. The rainy season commences in May or June and extends to November, followed by a markedly severe dry season. In both the Caribbean and Pacific lowlands, the average daytime temperatures are 28-33°C. The average temperature in the interior *Serranía* habitats (see Carr 1950) decreases with elevation and reaches highs of 30°C during the warmest months with 25°C during the coolest month. In montane areas, daytime temperatures range from 16-25°C with frost occurring occasionally above 2,000 m. At higher elevations, dense pine-oak forests predominate.

Ratcliffe and Cave (2006a) reviewed the different forest types of Mesoamerica, detailing more than 20 life zones found in El Salvador, Honduras and Nicaragua alone. In Honduras, there are six general forest types based on the Holdridge System (Holdridge 1967) that vary according to climate, associated vegetation and elevation. These include the montane broadleaf forest, montane pine-oak forest, tropical dry broadleaf forest, lowland broadleaf rain forest, lowland pine forest, and mangrove forest. These forest types vary with elevation and many unique microhabitats occur throughout Honduras. The forests in the Pico Bonito area are fragmentary with a mixture of primary and secondary rainforests including montane broadleaf, lowland broadleaf and pine forests. Montane broadleaf forest is characteristic of the intermediate and higher elevations of Pico Bonito National Park, with canopy trees at 25-30 m and an upper layer comprised of *Quercus* that may reach 50 m. Buttressed trees are common with tree ferns (Cyatheaceae) common in the understory. Palms are uncommon but species of Ericaceae and Melastomataceae are abundant as well as a number of epiphytes (gesneriads, aroids, bromeliads, orchids) and mosses covering rocks and tree trunks or limbs. Lower elevations in the park are dominated by lowland broadleaf forest, with a notable transition to palms and hardwoods with Magnoliaceae more frequently encountered.

Parque Nacional Pico Bonito and La Ceiba Vicinity

Our primary field site thus far is Parque Nacional Pico Bonito, with boundaries extending within both Atlantida and Yoro departments. It is part of the Sierra Nombre de Dios, which runs parallel to the northern (Caribbean) coast. Located to the west of La Ceiba, this is the second largest national park in Honduras, comprised of 1,314 km² and named for its third highest peak (Pico Bonito, 2436 m). However, there are two higher peaks in the park within the largely unexplored core area of 500 km², currently off limits for hiking. The rugged terrain is rocky with dense forests, rivers, waterfalls and abundant wildlife, including various mammals, a diverse herpetofauna and a very extensive avifauna (Perlo 2006). At lower elevations, the vegetation is tropical: mainly a mixture of sub-montane broadleaf evergreen forest of low to intermediate height with the canopy trees reaching 25-30 m. In some lowland areas, the landscape is dominated by agriculture with pineapple and oil palm as principal crops. However, there are areas with lush vegetation at lower elevations of the mountains that have been preserved.

History of Biodiversity Studies on Lepidoptera in Mesoamerica

Although Linnaeus, Walker, Butler, Schaus, Druce, and others described Lepidoptera from Central America in their respective works, it is the extraordinary work of Godman and Salvin (1877, 1878a,b,c, 1879-1901, 1889) which forms the basis for the Lepidoptera known at the time with descriptions of new species and superb illustrations. In their introduction, Godman (1901) summarized the various areas collected in each country and documented the primary collecting localities and/or those associated with each major collection, as in the case of Schaus. They noted the topography and major mountain ranges in each country and provided a general idea of the height of major summits, gave information on the location of the principal forests, and also recorded locations and conditions of the plains and drier areas. It is rather interesting that their description of Honduras is very limited, mentioning that the “general aspect of the country is varied by mountains and hills radiating from the common base of the Cordilleras...From the Pacific, it presents the appearance of a great natural wall, with a lower range of mountains bristling with volcanic peaks.” They state further that “the greater part of the country is well watered and extensive forests are said to exist in the interior, which, however, is but imperfectly known.”

Despite the expanse of time that has passed since Godman and Salvin, our voucher-based knowledge of the Lepidoptera fauna of Honduras remains incomplete and fragmentary at best. Within the last forty years, great advances have been made in recording distributions of Lepidoptera in other Mesoamerican countries surrounding Honduras. Austin et al. (1996) produced a checklist of butterflies of the Tikal National Park area, Guatemala, and Austin et al. (1998) and Barrios et al. (2006) inventoried the Hesperiidae of Guatemala. Salinas-Gutiérrez et al. (2009) published a historical synopsis of Lepidoptera collecting in Guatemala and summarized the current knowledge of species records and analyses of the Papilionoidea based on collection records, literature, fieldwork, and databases. Other recent studies have provided extensive information on the Lepidoptera fauna of southern Mexico and the Yucatan Peninsula (Pozo et al. 2003, 2008).

For Belize, Barnes (2002) has provided numerous moth records and images, and Meerman and Boomsma (1993) produced an initial checklist of butterflies. The latter was subsequently expanded by Meerman (1999). For the past 15 years, John Shuey and colleagues have been involved in studies on the biodiversity and conservation of the butterflies of the Rio Bravo Conservation and Management Area and other regions in Belize, resulting in many new butterfly records for the country. Shuey et al. (2005) reported 85 new national records for butterflies. Distributional information for Lepidoptera in El Salvador is limited, with an annotated list of the Hesperiidae of the country (Steinhauser 1975) being the only comprehensive faunal survey. Jean-Michel Maes (Museo Entomológico, Leon) and colleagues have been completing various inventories of insects in Nicaragua over the last 15 years with recent publications on the Papilionidae (Maes 2006), Pieridae (Maes 2007), and Hesperiidae (Anderson 2007).

Many studies have been completed on the Lepidoptera of Costa Rica. Based on fieldwork throughout Costa Rica, DeVries (1983, 1987, 1997) produced two excellent illustrated volumes on butterflies,

including detailed information on the distribution, life history, ecology, behavior and diversity of Costa Rican Papilionidae, Pieridae, Nymphalidae and especially Riodinidae (DeVries et al. 1994). More recently, Chacon and Montero (2007) published an introduction to the diversity of the Costa Rican Lepidoptera fauna, with descriptions of key characters for the identification of families, both immatures and adults. Janzen and Hallwachs (2010) have continued to improve our knowledge of Costa Rican Lepidoptera through mass rearings of many species in the Área de Conservación Guanacaste, including biological notes and illustrations of larval foodplants, immatures and adults. Janzen, Hallwachs and collaborators have combined molecular techniques with traditional morphological and ecological studies to identify a number of potentially new taxa (e.g., Burns and Janzen 2001, 2005a,b; Hebert et al. 2004; Burns et al. 2007, 2008; Janzen et al. 2009).

Although the diversity of plants in Honduras is relatively well known (Molina 1975; Sutherland 1986, 1996; Davidse et al. 1994, 1995, 2009), the Lepidoptera fauna of Honduras is the least known of any Mesoamerican country. Monroe et al. (1967) published the first list of the Papilioidea of Honduras, followed by a list of Hesperiidae by Monroe and Miller (1967). Fieldwork for these studies was restricted to areas near San Pedro Sula, from Tela along the northern coast, southeast to areas north of Tegucigalpa, with two collecting sites in the Department of Choluteca. Subsequent to these publications, there are scattered records from Honduras in revisionary studies completed by Miller (1972, 1974, 1976), Jenkins (1983, 1984, 1985a,b, 1986, 1989, 1990), Hall (1999), Willmott (2003) and many others. Hall noted Honduran records for five taxa of *Theope* Doubleday (Riodinidae). Willmott recorded 20 species of *Adelpha* Hübner (Nymphalidae) from Honduras in museum collections throughout the world; based on information derived from countries surrounding Honduras, he expected a total of 32 *Adelpha* species for the country. Warren et al. (2011) list and figure essentially all described Mesoamerican butterfly taxa, including all taxa known from Honduras, and provide images of live and pinned specimens from Honduras and surrounding countries.

Recent publications on Honduran moths have involved agricultural pests such as *Spodoptera* Guenée (Escribano et al. 2000a,b) and other members of the Noctuoidea (Gregory 1987; Sponagel and Díaz 1994; Cave 1992; Caballero et al. 1994; Ovalle and Cave 1989). Passoa worked in Honduras for a few years and produced several papers describing the hosts and immature stages for various moth taxa (Eichlin and Passoa 1983; Passoa 1982, 1983, 1985, 1991; Passoa and Habeck 1987; Passoa and Steinly 1992). Studies by Solis on the mahogany webworm (Howard and Solis 1989) and a pest of avocados (Solis and Styer 2003) have included data on immature stages of economically important Honduran Pyraloidea. Recent revisionary studies and catalogues on Pterophoridae (Gielis 2003, 2006), Pyraloidea (Munroe et al. 1995), Tortricidae (Brown 1996; Brown et al. 2005; Heppner 1995, 1996; Razowski 1986; Razowski and Becker 2007), Limacodidae (Epstein and Corrales 2004), Notodontidae (Thiaucourt 2002, 2007, 2008; J. S. Miller 2009a,b), and Arctiinae (de Toulgoët 1996, 1997) suggest that there should be additional species of those families represented in Honduras. Lehman (1971) published an initial list of the Sphingidae known from Honduras. Samayoá and Cave (2008) published an updated list for this family in Honduras, documenting 107 species. This publication increased the Honduran representation within the family by 33%, with new records represented in three subfamilies: Macroglossinae (80), Sphinginae (22), and Smerinthinae (5).

In 1996, Dr. Ronald Cave, then of Escuela Agric平ura Panamerica en Zamorano (EAPZ), initiated a major project to survey all insects in the protected forests of the Pico Bonito National Park and in other areas of the Sierra Nombre de Dios. This collection has been completely databased and is deposited in the Collection of Arthropods at EAPZ. Cave subsequently collaborated with Ratcliffe on revisionary studies of Mesoamerican Scarabaeidae (Ratcliffe 2000, 2001, 2003; Ratcliffe and Cave 2002, 2006a,b, 2008). Although major progress has been made, a comprehensive voucher-based inventory of the Lepidoptera within Honduras has not been completed. Among us, author Robert Lehman has been a resident and collected in and around La Ceiba for many years. His specimens, in part at the National Museum of Natural History, Washington, DC (USNM) and in the Museo de Mariposas, La Ceiba (RLMM), together with material at EAPZ, have comprised the most complete representation of the Honduran Lepidoptera fauna to date. Both EAPZ and RLMM are strongest in macrolepidoptera holdings. The microlepidopteran fauna of Honduras has, however, remained relatively unsampled and unstudied. Even within macrolepidoptera, for butterflies there has not been an updated species list for Honduras in almost a half a century (Monroe et al. 1967, Monroe and Miller 1967).

Our knowledge of the life history, ecology, and biogeography of Honduran Lepidoptera is woefully inadequate, compared to recent publications and information currently available on websites covering adjacent countries. Given the massive deforestation occurring throughout Mesoamerica on a daily basis (Tucker et al. 2005), we urgently need to improve our knowledge of the diversity and distribution of Lepidoptera species here before we miss the opportunity, especially with regard to potential endemic and key bioindicator species. The provisional list presented below is far from complete; however, we feel this is an important first step in establishing a foundation for our continuing inventory of the Lepidoptera of Honduras.

Acronyms and Museum Codens

Along with references to the authors by initials [JYM, DLM, TCE, CVC, RL], numerous institutional and locality acronyms are used in the text and list below. Four letter museum codens are: **EAPZ** = Escuela Agricultura Panamerica in Zamorano, Honduras; **MGCL** = McGuire Center for Lepidoptera and Biodiversity, Florida Museum of Natural History, University of Florida, Gainesville; **USNM** = National Museum of Natural History, Washington, DC; **RLMM** = Robert Lehman's Museo de Mariposas y Insectos, La Ceiba, Honduras. The following locality acronyms are also used in the text and list: **PBL** = The Lodge at Pico Bonito, La Ceiba, Honduras; **CURLA** = reserve property of Parque Nacional Pico Bonito managed by Centro Universitario Regional del Litoral Atlantico, Honduras; **ER** = The Honduran Emerald Hummingbird Reserve, Rio Aguan Valley, Olanchito, Honduras; **KC** = The Kellogg Center at Zamorano, EAPZ; **UYUCA** = Uyuca biological reserve of EAPZ; **CA** = Parque Nacional Cerro Azul, Meambar, Honduras. Reference is likewise made to records based on type localities [TL] and species included based on type localities of their current junior synonyms [TLS].

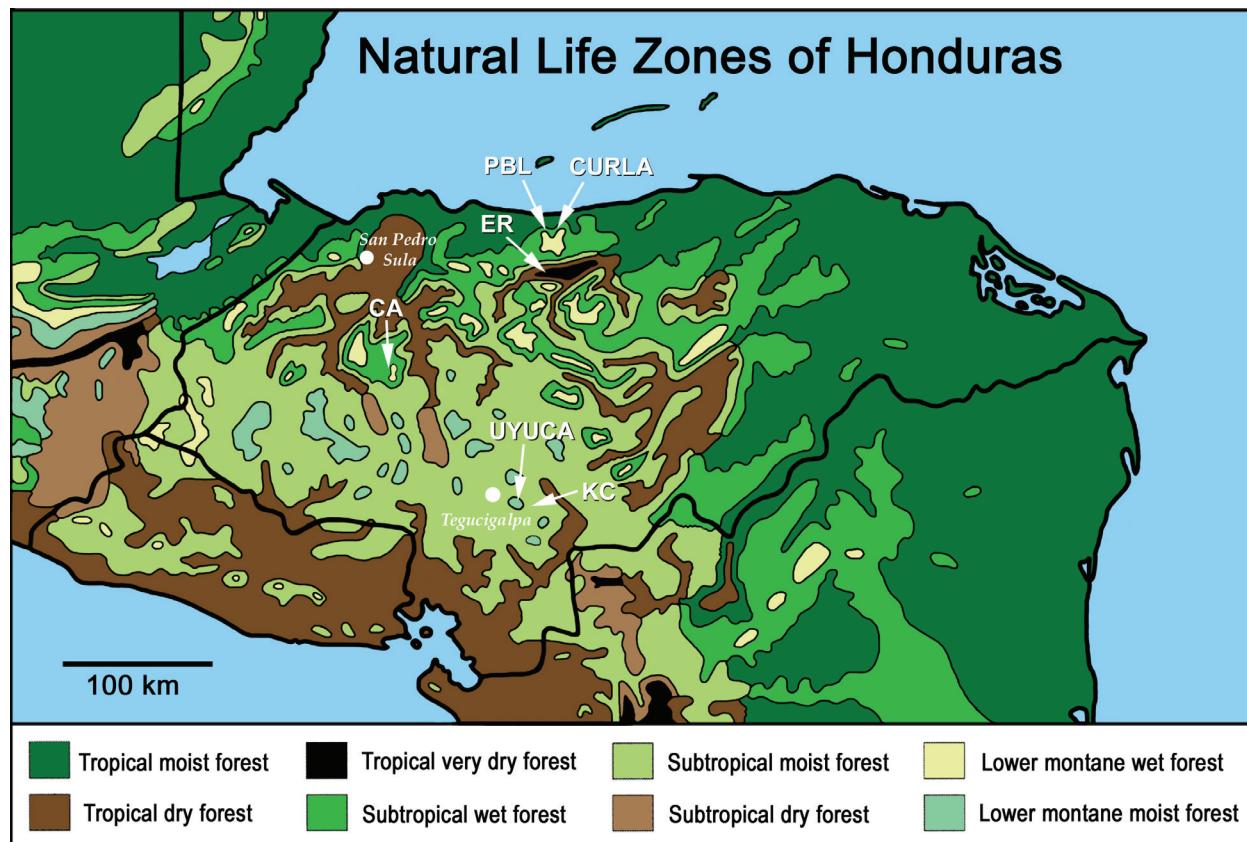

Methods

In June, 2009, a project was initiated by MGCL to survey the butterflies and moths along the northern coast of Honduras, concentrating in the area of Parque National Pico Bonito. Primary collection sites include habitats in the vicinity of the Lodge at Pico Bonito, Estación CURLA, and the Emerald Hummingbird Reserve, in the Rio Aguan Valley south of Pico Bonito (Map 1). Six trips to the area were made by MGCL staff, students, and field associates, with five trips in 2009-2010 devoted to collecting activities. Results of collecting trips are summarized in the present list by month and year. These included an initial collection based trip (23–30 June, 2009) by JYM and DLM with collections and/or species observed at the Kellogg Center of the EAPZ campus, Uyuca biological reserve of EAPZ, Parque Nacional Cerro Azul Meambar, and the Lodge at Pico Bonito. A second trip (9–16 November 2009) by JYM and DLM with two students was made to PBL and included surveys at CURLA with RL. A third trip (4–16 May 2010) by JYM and DLM with seven students/associates was made to PBL with additional collections at CURLA. Two trips were made in June (12–20 June 2010) by TCE and eight students/associates and (24–30 June 2010) by CVC and eight students/associates. The latter trip, led in conjunction with Forum Herbilot VI at MGCL, focused on the Geometridae. A subsequent trip (7–15 August 2010) by JYM and DLM and five associates included collecting at PBL, CURLA, and ER.

Our principal collecting site, PBL ($N\ 15^{\circ}\ 41'\ 48.00''\ W\ 86^{\circ}\ 54'\ 04.40''$), is located near the base of the mountains adjacent to Parque Nacional Pico Bonito at about 300 m (Fig 1). The property is bordered on the east and west by two rivers, Rio Corinto and Rio Coloradito, and consists of a 400 acre preserve with lowland tropical wet forest as well as coffee, cacao, banana and citrus groves. The CURLA reserve ($N\ 15^{\circ}\ 42'\ 07.00''\ W\ 86^{\circ}\ 51'\ 16.00''$) is located to the east of PBL and includes areas of pristine primary tropical forest. In contrast, ER ($N\ 15^{\circ}\ 25'\ 44.00''\ W\ 86^{\circ}\ 53'45.57''$) is located about 24 km due south of PBL in the rain shadow of the Sierra Nombre de Dios. This small reserve, part of a Honduran army military base, consists of tropical dry forest characterized by thorny scrub vegetation, unique with both cactus and orchids growing together and specialized nectar plants such as *Pedilanthus* Neck. ex. Poit. (Euphorbiaceae), which support one of the few populations of the endemic and endangered Honduran emerald hummingbird, *Amazilia luciae* (Lawrence).

Sampling methods involved hand collecting with nets as well as visual identification of easily identifiable diurnal species, bait traps containing fermenting fruit, and nightly collections at white

sheets illuminated by mercury vapor lamps or ultraviolet lights. While night collecting has thus far been at low elevations (< 500 m), collecting at PBL was especially productive with mercury vapor lights set at the top of a four-story bird observation tower in view of the Rio Coloradito and surrounding mountains. All specimens were pinned, spread, and labeled, and deposited at MGCL with voucher specimens also deposited at EAPZ and USNM. Legs have been removed from selected specimens for subsequent DNA extraction and analysis. Tissue samples are stored at the Genetic Resources Repository at the Florida Museum of Natural History.

Map 1. Natural Life Zones of Honduras (modified from Ratcliff and Cave 2006a, with permission) showing forest types and location of collection/observation sites. See text above for location acronyms.

Specimens were identified based on comparison with identified reference material at USNM, MGCL, and EAPZ, as well as types or type images, primary literature accounts included in revisionary studies, and older literature such as Cramer (1775-1782), Godman and Salvin (1879-1901), Seitz ([1907]-1924), Hampson (1898-1913, 1914, 1920), Druce (1881-1900, 1888), Walsingham (1915), and more recent works such as Lemaire (1971, 1973, 1974, 1978, 1980, 1988, 2002). Several internet websites have been especially helpful with nomenclature and in obtaining initial identifications and corroborating determinations. Some examples of these include: Warren et al. (2011), Moth Photographers Group (2011), Janzen and Hallwachs (2010), Barcode of Life Data Systems (2011), Lahousse (2011), Barnes (2002), Smithsonian Institution (2011), Nuss et al. (2003-2011), and Phillips (2001).

In addition to records resulting from recent collecting efforts, Honduran species found in primary literature and collection records of EAPZ, USNM, MGCL, and RLMM are incorporated into the present list. Examples of general literature accounts yielding numerous records and type locality references include Druce (1881-1900), Kirby (1892), Schaus (1920) and Walker (1854-1866), and some examples of works focused on particular taxa with multiple records included Davis (1964), Pitkin (1993, 1996), Poole (1987, 1989), Powell (1973), Scoble (1999) and numerous others.

Annotated List of Honduran Lepidoptera

The provisional species list presented in table format below is a product of our ongoing biodiversity inventory. Additional taxa are expected in future field surveys. Each taxon is annotated to indicate the source of voucher specimens, sight or collection locality records, or type localities using the acronyms and codens listed above. Taxa included without annotations are based on records found in the literature. Nomenclature and systematic arrangement for butterflies generally follow Warren et al. (2011), Pelham (2008), and/or Lamas (2004). Nomenclature and systematic arrangement for the moths generally follows or is adapted from recent revisionary works and checklists including Lafontaine and Schmidt (2010) for Noctuoidea, Watson and Goodger (1986) for Arctiinae, Scoble (1999) for Geometroidea, and the *Atlas of Neotropical Lepidoptera* series (Heppner 1984, 1995, 1996) for Pyraloidea and other groups. While we are aware of conflicting nomenclature with the ongoing systematic research of colleagues, our list includes names, subfamilial, and tribal assignments based on published works only. Collection or sight records from recent surveys are marked with an “x” for each species in columns to the right of the name according to the month and year: **1)** 06/2009, **2)** 11/2009, **3)** 05/2010, **4)** 06/2010, **5)** 08/2010. Author names are spelled out except in one case (F. M. Brown [FMB]) where it was necessary to use initials to maintain the single line format of the row. Subfamilial and tribal names are included in taxa where this facilitates the understanding of the ordering of the list.

NOTES:

A1 – Identification in EAPZ database questionable. Specimens from the TL only in USNM. These may be the very similar *H. drucei* (Schaus, 1910), from Guatemala and Costa Rica.

A2 – Identification questionable: USNM has phenotype (as illustrated in Seitz) from Peru and Brazil.

Results and Discussion

While our inventory of the Lepidoptera of Honduras is far from complete, our initial results and comparisons with previous records provide insight into the expected diversity and potential evidence of endemism. Our fieldwork to date has been based primarily at the Lodge at Pico Bonito and other areas along the northern coast near La Ceiba. Moth collecting has also been centered at the Lodge at Pico Bonito. Moth groups well represented in our nocturnal samples include the Pyraloidea (principally Crambidae), Noctuoidea, especially Arctiinae and Notodontidae, Geometridae, Sphingidae, and Saturniidae. Thus far, excluding undetermined material, more than 975 species of moths have been collected during our surveys, with the addition of literature and museum specimen records producing a total of 1,441 moth species included in the present list for Honduras. The highest diversity has been within the Pyraloidea and Noctuoidea, with many species represented by single specimens. A total of 861 butterfly species are now listed for Honduras, with 393 species collected during our surveys. In all, 2,302 species of Lepidoptera are recorded herein. Based on comparison with the work of Janzen and Hallwachs (2010, pers. comm.) for Costa Rica and our current findings, we estimate the total number of Lepidoptera species in Honduras will exceed 6,000. Some representative taxa of butterflies (Fig. 2-9) and moths (Fig. 10-36) sampled during our surveys are illustrated. However, we hope to provide reference images for many additional species, either web-based and/or in subsequent publications.

In summarizing our preliminary results for various moth taxa, we note the Pyraloidea are particularly diverse with 290 species listed, and many samples are still undetermined. Several new species are present in our material, some of which are also found in other parts of Central America, such as Área de Conservación Guanacaste, northwestern Costa Rica, and await revisionary studies

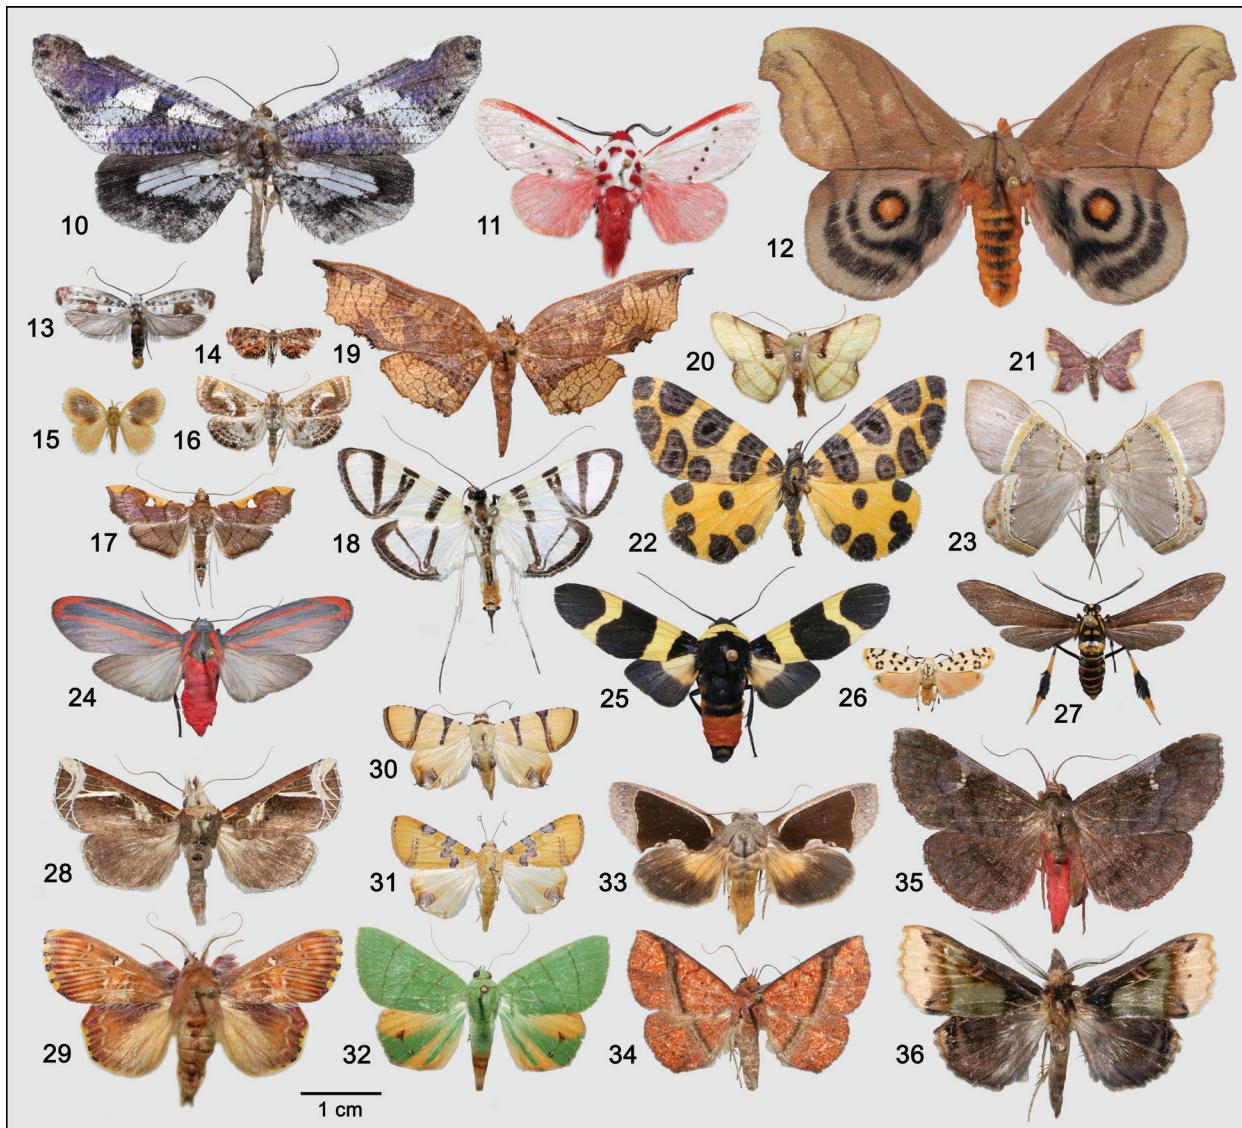

Figures 2-9. Honduran butterflies. 2) *Pareuptychia ocurrhoe*. 3) *Calephelis* sp. 4) *Charis anius*. 5) *Parides eurimedea mylotes*. 6) *Cymaenes trebius*. 7) *Strymon ziba*. 8) *Calospila cilissa*. 9) *Vehilius stictomenes illudens*.

of the various genera. Not surprising, given the proximity to two rivers, the aquatic Crambidae (Acentropinae) are especially abundant at PBL with 27 morphospecies distinguished, 11 determined to named species thus far and 11 recognized as probable new species. While only 29 species of Gelechioidae are indicated in our list, material representing this group includes many additional species to be sorted and identified. In the Glyphidoceridae alone, Adamski (pers. comm.) recognized four

new species that he will describe in a forthcoming publication. Other microlepidopteran groups, such as the Tortricoidea, are poorly represented in both numbers of species and the number of individuals collected. The Tortricidae do, however, hold some interesting surprises, with colorful, elaborately patterned diurnal genera such as *Pseudatteria* Walsingham and *Mictopsichia* Hübner. In the later genus, Matthews et al. (2011) reported the occurrence of *M. cubae* (Fig. 14) from our surveys, noting the new country record, biogeographical significance, and describing the previously unknown female genitalia and evasive behavior of adults.

Some progress has been made in our knowledge of the Pterophoroidea with additional work to be completed. Literature accounts for Pterophoridae (Walsingham 1915; Gielis 2003, 2006) indicated

only six species from Honduras, while 46 and 15 species are recorded from Costa Rica and Guatemala, respectively. Matthews and Lott (2005) reviewed and catalogued larval foodplants of the world's Pterophoridae. While 70 plant families are utilized, one-third of pterophorids for which larval foodplants are known are associated with Asteraceae. Based on the diversity of the Asteraceae species found in the Herbario Zamorano Paul C. Standley, EAPZ, from Honduras (410 species) (database records, courtesy of Director, Dr. George Pilz) and comparison with the adjacent Central American faunas and the Nearctic fauna (159 species, Matthews 2006), the Honduran fauna of Pterophoridae should approach or exceed 50 species. After examination of material in the collections at EAPZ and our recent surveys, we now recognize 17 species of Pterophoridae from Honduras with 12 named species, and the remainder determined to genus. At least two species are known to be new, with descriptions in preparation by Matthews and Miller. In addition, Matthews and Miller (2010) recently described the life history of the cacao plume moth, *Michaleophorus nubilus* in Honduras, also noting the new record for the country.

The major macro moth groups (Zygaenoidea, Coccoidea, Sesioidea, Lasiocampoidea, Bombycoidea, Geometroidea, Noctuoidea) account for 1,055 or 73% of the 1,441 moth species listed, with 674 of these represented by our recent fieldwork. Among the generally diurnal taxa, the Castniidae (Castniinae) are poorly known from Honduras. Originally, there were only a few Honduran records in collections of *Telchin atymnus futilis* and *Athis i. inca*. No specimens of the latter have been observed during our surveys as yet, but *T. atymnus futilis* has been frequently encountered along the northern coast at PBL and CURLA. In addition, specimens of another species, *Divana diva*, a species widely distributed throughout Central America, are known from PBL and also collected by RL (RLMM). Specimens of *Athis clitarcha*, originally described from Panama (Salvin) and Nicaragua (Belt) (Miller 1986), have also been collected in Honduras (RLMM and EAPZ). *Amauta cacica procera* was originally described from Guatemala, with most specimens in museum collections recorded from Chiriquí in Panama (Miller and Sourakov 2009). This species has been observed by Janzen in eastern Costa Rica (pers. comm.) and collected in Honduras (RLMM and EAPZ). Another species, *Telchin licus*, has not been previously recorded in the literature north of Panama, but it has also been collected in Honduras (RLMM and EAPZ). This species, an agricultural pest normally associated as larvae with various *Heliconia* and sugar cane in South America (especially Amazon basin), appears to be well established in the Pico Bonito National Park and elsewhere along the northern coast of Honduras. This latter species has obviously extended its geographic range or possibly was introduced to the area. We believe that with continuing surveys at least another two to four species of Castniidae will be found to occur in Honduras.

The Noctuoidea are thus far represented by 561 species, primarily Erebidae (386 species). While most have been collected at lights, a few, such as *Ascalapha odorata*, were commonly found in bait traps. We have also observed *Azeta rhodogaster* (Fig. 35) during the day on a regular basis, easily spotted in flight by the red abdomen. The larvae of this species feed on the "living fence" tree *Gliricidia sepium* (Fabaceae) which is very common in northern Honduras and elsewhere in Central America. Also encountered during the day at PBL and CURLA were several dioptines (Notodontidae), including *Oricia truncata* and *Josia*, *Phanoptis*, and *Phaeochlanena* spp., the latter along with several of the nocturnal genera in our material containing undescribed species and in need of careful study (James Miller, pers. comm.). Certain erebid genera such as *Eulepidotis* (12 species) of the Eulepidotinae and *Gonodonta* (10 species) of the Calpinae are notably diverse at PBL, but the Arctiinae are overall the most diverse with 210 species listed for Honduras and 131 collected at PBL. While some of the striking wasp mimics of this group are frequently encountered at the sheet, such as *Horama plumipes*, others, for example, the widespread species *H. oedippus* (Fig. 27), are represented by single specimens. Some genera such as *Macrocneme* are numerous at the sheet but though first appearing as single species, show slight variations in the maculation and metallic hues on the black forewings, with cryptic species likely involved. One of our most significant finds in the Arctiinae is a single specimen of *Euthyne theodula* (Lithosiini), previously known only by the Schaus holotype from Guatemala in the USNM.

The Geometroidea are another sizeable group with 215 species recorded for the country and 161 collected at PBL. Several species are more or less ubiquitous, present in large numbers at the sheet during each sampling period. Examples include three species of *Synchlora* Guenée, *Tricentrogyna violescens* (Fig. 21), *Pyrinia sanitaria*, *Patalene aenetusaria*, *Oxydia vesulia*, and *Leuciris fimbriaria*.

Certain genera such as *Macaria* and *Eois* are common and will undoubtedly add named species to the list with further identification work including dissections of genitalia and comparison with type material. Revisionary studies such as Poole (1987) and Pitkin (1993, 1996) have greatly contributed to the known fauna. Further collecting and identifications by CVC and others as well as the results of ongoing barcoding work by research associates visiting PBL in June 2010 in collaboration with the Biodiversity Institute of Ontario are also expected to contribute markedly to our knowledge of the Honduran fauna.

During the last two years, our surveys have sampled the overall lepidopteran biodiversity but due to the limitations on the total numbers of collected specimens permitted per trip and space considerations in transport, we have focused on many of the smaller moths. However, within the Bombycoidea, we have collected several Bombycidae (7) and have voucher specimens and other records for 82 Saturniidae. Although Ronald Cave and Robert Lehman have collected a number of the Hemileucinae during their respective surveys, we have not yet collected voucher specimens for many of these species. However, *Schausiella santarosensis* was a remarkable find, collected in November during some rather heavy rains. In reviewing the literature and other records, it is surprising that *Copiopteryx semiramis* has not been reported in literature accounts for Honduras. This genus is rather uncommon in the field, but conspicuous because of the long tails. Meerman (1999) listed it for Belize and there is a single specimen from Honduras in EAPZ. The diversity of another major bombycoid lineage, Sphingidae, at PBL is remarkable with about half (50) of the total number of known Honduras species (112) present.

Within the butterflies, the number of known Mesoamerican Hesperiidae (combined species and subspecies) is rather remarkable. Evans (1951, 1952, 1953 and 1955) listed 223 species of Hesperiidae from Honduras, while Munroe and Miller (1967) recorded 83 species, many of which were new national records at the time. ADW (unpublished) conducted an analysis of species represented in literature and collections, and the results are indicative of how few biodiversity surveys have been completed in some areas of Mesoamerica. Records for Hesperiidae in Central America were as follows: Mexico 792, Belize 282, Guatemala 391, El Salvador 283, Nicaragua 366, Costa Rica 589, and Panama 448. Including our recent field data, the total number of Hesperiidae now recorded for Honduras stands at 311 species. Based on the analysis of Mesoamerican distributions (ADW), we expect up to 587 taxa of Hesperiidae to eventually be found in Honduras, suggesting that as much as 47% of the country's hesperiid fauna remains to be documented. This number may at first seem unusually high, but the discovery of 35 undescribed hesperiid taxa from Mexico within the last 15 years, coupled with at least that many new hesperiid taxa recently discovered in Costa Rica (Burns and Janzen 2001, 2005a,b; Burns et al. 2007; Hebert et al. 2004; Janzen and Hallwachs 2010; Pozo et al. 2008; Warren et al. 2011), reinforces the fact that there is much to learn about the distributions and diversity of Mesoamerican Hesperiidae, especially those of high-altitude habitats, which are very poorly known for Hesperiidae and other groups in Honduras.

Compared to the Hesperioidea, there are fewer new additions in the Papilioidea with a total of 550 taxa recorded for Honduras, 267 for which we have collected voucher specimens during our 2009-2010 surveys. There are a number of potential additional species recorded for the country, but often these are taxa which have been recorded from surrounding countries and not been previously published elsewhere. Some of the most noteworthy new records include *Ostrinotes purpuriticus*, *Strephannota sphinx*, *Euselasia h. hieronymi*, *Ectima erycinooides*, and *Oxeoschistus tauropolis*. The butterflies provide some interesting statistics with respect to the overall species biodiversity. For example, in the Riodinidae, there are 101 vouchered or potential taxa for Honduras and of these, we have identified and collected 50 taxa thus far. Some species such as *Calospila cilissa* and *Juditha caucana* appear to have multiple broods throughout the year and were present at PBL during our surveys in May, June, August and November. Other interesting species in this group include *Leuchochimona lepida nivalis*, *Peropthalma tullius*, *P. lasus*, and *Notheme erota diadema*. While there is great diversity in the genus *Calephelis*, some problematic specimens remain undetermined. Although members of this family did perch on the under surface of plants, we observed a number taking nectar on flowers in open sunny patches both at PBL and CA. Thus far, 50 Riodinidae and 51 Lycaenidae have been identified from our recent studies in Honduras compared with 49 Riodinidae and 101 Lycaenidae identified by Austin et al. (1996) from Tikal, Guatemala.

Several butterflies, including Lycaenidae (Eumaeini) and Hesperiidae (Eudaminae), were collected at mercury vapor lights at night. Among these are *Cyanophrys fusius*, *Brangas neora*, *Bungalotis astylos*, *Dyscophellus phraxanor*, and *Polygonus s. savigny*. Only the latter species was also collected during the day. This source of sampling should not be overlooked since the crepuscular skippers and canopy dwelling lycaenids, such as *B. neora*, might not otherwise be readily encountered.

As previously noted, our list is by no means complete, especially for the moths, with only a fraction of the expected number of species represented for the country. Future survey work must extend to other areas of the country, and include sampling at higher elevations and in a greater variety of habitats. Even for PBL, it will be necessary to continue sampling with multiple techniques over the course of several years and throughout the year, to include the variation of seasonal wet/dry cycles, periodic heavy rainfall from Atlantic tropical systems, as well as rain shadow effects of mountains in the vicinity. Along with more extensive sampling, there are also problems to overcome with species-level identifications. Most of our determinations of moths are based on comparisons with species known from Guatemala, Belize, and Costa Rica, using limited literature, internet, and collection resources. For many of the taxa listed, we have, unfortunately, had to resort to using genus plus "sp." or "nr." (near) as a means of recording our results. While we have been able to determine most taxa to genus, there are still numerous morphotypes to be sorted out and classed as numbered unknowns in Gelechioidea, Noctuoidea, and likewise for several pyraloids, altogether representing approximately 170 species.

Although many of the low elevation species encountered thus far are broad-ranging and occur throughout Central America and much of the rest of the Neotropics, there are still overriding questions as to whether or not these similar phenotypes are indeed the same genotype or monophyletic species from one area to the next. Ultimately, DNA barcoding and morphological studies may help resolve some of these problems, including cases of cryptic sympatric species. However, especially for moths, many of the species we have identified were described by Walker, Druce, Schaus, and others more than 80 years ago and previously known only from the holotype specimens. Thus, while barcoding may separate close species, unless genomic sequences can be successfully obtained from these relatively old holotypes, final decisions on nomenclature will have to be based on morphology alone. This problem is further compounded by the need to examine the types of multiple synonyms already established for many neotropical species.

As our work continues and the list of species is refined through revisionary studies, there will be many other aspects of the natural history and biodiversity of Honduran Lepidoptera to further explore. Janzen and Hallwachs (2010) and collaborators have produced remarkable websites and long-term studies documenting the life histories of Guanacaste Lepidoptera in Costa Rica, and it is hoped that similar, if less extensive, efforts can be made at PBL in collaboration with staff, students, and parataxonomists. In many cases the best approach to life history studies may be to survey the associates of specific larval food plants. In general, our surveys of adults have been strictly qualitative, with the primary objective of assembling faunal lists and recognizing new records, undescribed and/or endemic taxa. We hope that this work will provide baseline data for more quantitative studies by future researchers investigating biodiversity patterns and trends in comparing areas based on elevation, microhabitat, environmental quality, climate change, and other factors used in recognizing critical areas for conservation management.

We have not yet assembled sufficient data to be able to make predictions on the number of endemic taxa to be expected for Honduras. This is due in part to working at low elevations, and limited sampling in isolated habitats such as the tropical dry forest habitats similar to the ER. We are aware of several new species from Honduras, though some are recognized as also occurring in other areas of Central America. In a few cases, such as in the Pterophoridae, though not necessarily endemic, the new species are known from Honduras only from PBL specimens.

Honduras, as a critical part of the Mesoamerican biodiversity "hot spot" has much to offer in the study of Lepidoptera and other organisms. In addition, studies of fluctuating distributions and evolutionary divergence patterns of taxa in Central America and the Caribbean Basin can provide insight to our understanding of phylogenies and divergence patterns within higher taxa. The present listing of taxa and review of previous works provide a foundation for further surveys and studies in the area. We welcome additions and corrections to the present list for future updates and encourage

individual publications of faunal records, life history studies, and revisionary works including material collected from past, present, and future surveys. This work not only contributes to science in general, but serves to increase the value and appreciation of the natural resources of this country for future generations of Honduran citizens.

Acknowledgments

We gratefully acknowledge Jose Manuel Mora Benavides, Director of the Biodiversity Center, and Oliver Schlein, Escuela Agric平tura Zamorano, Honduras, for their invaluable assistance in making the facilities and the collection resources of the EAPZ available to us and aiding us with the permitting process. Permits for collection and export of study material were granted through Instituto Nacional de Conservaci平n y Desarrolla Forestal, 阿rea Protegidas y Vida Silvestre, Honduras. We have benefited from discussions with Ronald Cave, formerly of EAPZ, and now in the Department of Entomology and Nematology, University of Florida. Ron, along with Oliver Schlein, and George Pilz graciously shared information concerning the EAPZ collections and databases and also provided us with details on various collecting localities throughout Honduras. We are indebted to James Adams and the staff and directors of The Lodge at Pico Bonito, for their hospitality and for providing us logistical assistance in completing our surveys. We also thank Juan Alberto Hernández and Kelvin W. Bodden, Centro Universitario Regional del Litoral Atlantico for access to the CURLA reserve at Parque National Pico Bonito. Special thanks are due to J. Court Whelan and James B. Schlachta for assistance with travel arrangements.

In addition to the respective contributions of the authors, several colleagues, including Ulf Eitschberger, James K. Adams, James Hayden, Terry Dickel, and David Adamski, generously provided multiple determinations of species in their respective areas of expertise. Our communications with Dan Janzen and Winnie Hallwachs have also given us insight into the overall diversity in the region and the potential for undescribed species in various taxa. Authors JYM, DLM, TCE, and CVC would also like to thank the following individuals who provided good-humored camaraderie in the field, assisted with our field work, and/or supplied specimens and/or determinations resulting from their respective collecting activities in Honduras: Eric Anderson, Eddie Atamian, David Auth, Jorge Chavarria Bertrand, Kelvin Bodden, David G. Bridgnell, William H. Bridgnell, Richard C. Cramer, Chad T. Douglas, Collin M. Douglas, Matt Lehnert, Ron Leuschner, James Hanlon, Lowell N. Harris, Lawrence R. Hummer, Chris Livesay, David G. Marqua, Gerald M. McWilliams, Linda S. McWilliams, Iva Mihoci, Carlos Montúfar, Alfred Moser, Thomas V. Myers, Ichiro Nakamura, Bedros Orchanian, Arthur Ortegon, Tony Ortegon, John G. Pasko, Christian Salcedo, Ana Clariza Samayo, Ian K. Segabarth, Bradley A. Stirn, Jon D. Turner, Nancy C. Turner, Gerald S. Wagner, J. Court Whelan, and Eckhard Wierig. MAS wishes to thank Mark Metz for support on the Pyraloidea.

Finally, and not in the least, we wish to thank James K. Adams, Dalton State College, Dalton, Georgia, Manuel A. Balcázar-Lara, Universidad de Colima, Mexico, Terry A. Lott, Florida Museum of Natural History, Paul E. Skelley, Florida State Collection of Arthropods, and Jennifer Zaspel, University of Wisconsin, Oshkosh for their helpful comments in improving the text, format, and content of the paper.
