

**IDENTIFICATION OF BIOMARKERS FOR  
THE FRUITING BODY FORMATION IN  
*MYXOCOCCUS XANTHUS***

Dissertation

zur Erlangung des Doktorgrades

der Naturwissenschaften

vorgelegt beim Fachbereich für Biowissenschaften (15)

der Johann Wolfgang Goethe - Universität

in Frankfurt am Main

von

Wolfram Lorenzen

aus Berlin

Frankfurt 2014

D 30

vom Fachbereich für Biowissenschaften (15) der

Johann Wolfgang Goethe - Universität als Dissertation angenommen.

Dekanin: Prof. Dr. Anna Starzinski-Powitz  
Gutachter: Prof. Dr. Helge B. Bode  
Zweitgutachter: Prof. Dr. Dieter Steinhilber  
Datum der Disputation: 16.12.2014

# Danksagung

Meinem Doktorvater, Mentor und Chef Professor Dr. Helge B. Bode möchte ich besonderen Dank für die Betreuung und Unterstützung meiner Projekte aussprechen. Mit seinem aufrichtigen Interesse, seinen Beiträgen aus seinem schier unerschöpflich erscheinenden Schatz aus Wissen und Erfahrung, seinem permanenten Einsatz und Ideenreichtum stets Möglichkeiten zur Bewältigung neuer Herausforderungen zu schaffen hat er mehr als nur die Grundlage meiner Forschungsprojekte gesichert. Unvergessen bleibt auch sein in wenig aussichtsreichen Phasen unerschütterliches Vertrauen in den Erfolg meiner Projekte.

Meinen „Saarbrücker“ Mitstreitern Dr. Daniela Reimer, Dr. Michael W. Ring, Dr. Alexander O. Brachmann, Dr. Carsten Kegler und Gertrud Schwär danke ich für deren Unterstützung bei der Einarbeitung in die Mikrobiologie, Molekularbiologie und ersteren Beiden für die Unterstützung bei der HPLC-MS bzw. technische Einarbeitung in die GC-MS Analytik. Meinem einzigen „Myxo-“ Mitstreiter in Frankfurt Tilman Ahrendt möchte ich meine Verbundenheit dafür ausdrücken, dass er sich mutig und mit großem Einsatz in dieses Arbeitsfeld gewagt hat und stets für eine positive Stimmung im Labor gesorgt hat. Kenan A. J. Bozhüyük gebührt mein Dank für die erfolgreiche Lösung selbst spitzfindigster Bioinformatikherausforderungen und Dr. Dominic Bäumlisberger, Dr. Sebastian W. Fuchs und Dr. Marion Rohmer danke ich für ihre fundierte Hilfe bei meinen MALDI-MS Messungen.

Darüber hinaus danke ich allen aktuellen und ehemaligen Mitgliedern der Arbeitsgruppe Bode für die freundliche und produktive Atmosphäre während der vielen Jahre und wünsche ihnen, wie auch meinen ehemaligen Kooperationspartnern Dr. Silke Schmidt, Dr. Florian Hilbers, Dr. Frederik Barka und Dr. Dawid Brat eine glückliche und erfolgreiche Zukunft.

Herrn Professor Dr. Dieter Steinhilber danke ich ganz herzlich für die Übernahme der Zweitgutachterfunktion, sowie Alexander J. Perèz und Tilman Ahrendt für die produktiven Kommentare und das wachsame Auge bei der Überarbeitung dieses Manuskriptes.

All meinen Freunden möchte ich schließlich meine tiefe Verbundenheit für all die erhellenden Erlebnisse und vertrauensvollen Gespräche aussprechen.

## Table of abbreviations

ACP	acyl carrier protein
AEPE	1- <i>O</i> -(13-methyltetradecyl)-2- <i>O</i> -(13-methyltetradecanoyl)glycero-3-phosphatidylethanolamine
a.k.a.	also known as
ATP	adenosine triphosphate
BCKAD	branched-chain-2-oxo-acid dehydrogenase complex
CDP	cytidine diphosphate
DMAA-CoA	3,3-dimethylacrylyl-Coenzyme A
DMAPP	dimethylallyl diphosphate
e.g.	exempli gratia
ELK	eukaryotic-like protein kinase
G protein	guanosine nucleotide-binding proteins
GC-MS	gas chromatography coupled with mass spectrometry
GPCR	G-protein-coupled receptor
3-HMG-CoA	3-hydroxymethylglutaryl-Coenzyme A
Ile	isoleucine
IP <sub>3</sub>	inositol-1,4,5,-trisphosphate
IPP	isopentenyl pyrophosphate
IV-CoA	isovaleryl-Coenzyme A
(HP)LC-MS	(high performance) liquid chromatography coupled with mass spectrometry
Leu	leucine
MAPK	mitogen activated protein kinase
3-MG-CoA	3-methylglutaconyl-Coenzyme A
NAD <sup>+</sup>	nicotinamide adenine dinucleotide

NRPS	non-ribosomal peptide synthetase
PAF	platelet-activating factor
PCA	principal component analysis
PCD	programmed cell death
Phe	phenylalanine
PIP <sub>2</sub>	glycerophosphoinositol-4,5-bisphosphate
PKA	protein kinase A
PKC	protein kinase C
PKS	polyketide synthase
ROS	reactive oxygen species
SCAD	short-chain dehydrogenase
SEM	scanning electron microscopy
TG-1	1,2-di-(13-methyltetradecanoyl)-3-(13-methyltetradecyl)glycerol
TMS	trimethylsilyl ether
Trp	tryptophan
Tyr	tyrosine
UPLC-ESI-MS	ultra performance liquid chromatography coupled with mass spectrometry after electrospray ionization
UPLC-MS	ultra performance liquid chromatography coupled with mass spectrometry
VEPE	1- <i>O</i> -(13-methyl-1- <i>Z</i> -tetradecenyl)-2- <i>O</i> -(13-methyltetradecanoyl)glycero-3-phosphatidylethanolamine

## Summary

Bacteria are generally considered as more or less “simple” organisms due to their unicellular live style lacking the ability to form differentiated tissues that feature labor division. However, intercellular communication using specific signaling molecules, generally termed as “quorum sensing”, is known from several prokaryotic species. Additionally but to a limited extend, cell differentiation and tissue formation are known for example from actinomycetes (aerial mycelium formation) and cyanobacteria (heterocyst formation).

A remarkably sophisticated example for cell differentiation and complex intercellular communication can be found within the order of the myxobacteria. These Gram-negative, soil dwelling bacteria feature an impressive number of properties: they can glide on solid surfaces by using two different motility motors, subsist by preying on other microorganisms, are often producers of multiple natural products, and upon adverse environmental conditions, they are able to form multicellular structures called “fruiting bodies”. Their complexity ranges species-specifically from simple mounds to maddish, tree-like forms. The process, in which these macroscopically visible structures arise from independent single cells, has been the predominant subject of myxobacterial research for many decades. More precisely, researchers have strived for the discovery of genes, proteins and small molecules that act as signals, receivers or modulators of this complex process. In this regard, the species *Myxococcus xanthus* has evolved into the model organism due to its relatively simple and reliable handling in a laboratory environment. The research underlying this thesis focused on the identification and biosynthesis of lipids that may act as signaling molecules as part of the “E-signal” system. In general, lipids containing branched-chain fatty acids with an uneven number of carbon atoms were found to be important players in the process of fruiting body formation and sporulation. Nevertheless, their exact roles remain largely unknown.

The first publication that is part of this thesis deals with an aspect that even strengthened the importance of role of iso-branched compounds in myxobacteria: myxobacterial metabolism is able to transform precursors of iso-lipids to isoprenoids. It addresses the question whether isoprenoids in general are important for fruiting body formation. Phenotypic analysis of mutants impaired in the biosynthesis of the central isoprenoid precursor 3-hydroxymethylglutaryl-Coenzyme A (3-HMG-CoA) from acetate and/or

branched chain keto acids and their genetic and metabolic complementation clearly showed that isoprenoids are essential for fruiting body formation and confirmed that leucine derived isovalerate is an important source for isoprenoid precursors in myxobacteria.

The second, and by far and away most tedious and sophisticated study, addressed the question as to how myxobacteria form fatty acid derived iso-branched ether lipids and to what extent they are important for fruiting body formation and sporulation. In a previous study, those unusual lipids were identified as specific biomarkers for myxobacterial development. No biochemical pathways to ether lipids specific for prokaryotes were known by then. In this study, a putative candidate gene that may be involved in ether lipid biosynthesis was investigated. A combination of gene disruption and complementation experiments, phenotypic analysis and monitoring of ether lipid formation by means of GC-MS demonstrated its involvement in myxobacterial ether lipid biosynthesis and the importance of these lipids for the developmental process. Heterologous expression and biochemical testing of this gene together with *in-silico* sequence analysis and docking experiments confirmed the functions of its predicted domains. The discussion section provides an additional suggestion on how the ether bond formation is performed. Furthermore and most importantly, iso-branched ether lipids were found to be essential for sporulation but not for fruiting body formation. In summary, one or several molecules derived from an iso-branched alkylglycerol seem to play a role during sporulation in *M. xanthus* and a multidomain enzyme unique for myxobacteria is involved in their biosynthesis.

The last manuscript addresses the complexity of lipid metabolism in myxobacteria. Prior to this work, there was limited knowledge about the exact composition of the myxobacterial lipidome and no method was available to monitor putative changes in the myxobacterial lipidome down to the single molecular species for studying lipid biosynthesis or regulation. An ultra-performance liquid chromatography coupled with mass spectrometry based method with electrospray ionization (UPLC-ESI-MS) utilizing standard equipment and a water/acetonitrile/isopropanol based eluent system proved to be geared for the construction of lipid profiles for wild type and mutant cells of *M. xanthus* and to show their differences. Fragmentation spectra based structure elucidation of lipid molecular species resulted in the identification of 99 molecular species comprising glycerophosphoethanolamines, glycerophosphoglycerols, glycerolipids, ceramides and ceramide phosphoinositols. The

latter have never been described for any prokaryotes before. Three dimensional plots were created from the relative intensity differences of the single molecular ion species between the different samples to provide an efficient and versatile visualization of the data and enable the researcher to quickly detect differences.

# Zusammenfassung

Mit der Entdeckung des Lichtmikroskops erschloss sich Forschern zunehmend eine vollkommen neue, vorher unvorstellbare Welt von überwiegend einzellig lebenden Organismen. Im Laufe der Zeit stellte sich deren Einfluss auf das menschliche Leben als immens heraus, wenn man nur die Bedeutung von Bakterien und Pilzen in der Zubereitung von Lebensmitteln einerseits und deren Verantwortung für die Entstehung von zum Teil schwerster Infektionskrankheiten andererseits bedenkt. Die wahrscheinlich größte Vielfalt von Mikroorganismen lässt sich im Erdboden finden. Auf kleinsten Raum ringen hier hunderttausende von Arten um Ihr Fortkommen, wobei jede Ihre eigenen Strategien entwickelt hat, um sich einen ausreichenden Zugang zu Nahrung, Platz und Schutz vor Fraßfeinden zu verschaffen und das Überleben während der sich ständig ändernden Umweltbedingungen zu sichern. Dazu gehört die Produktion nieder- und hochmolekularer Substanzen, die als Toxine oder hormonähnliche Signale agieren können. Die Umwandlung von Zellen in stoffwechsellinaktive, hitze-, kälte- und trockenheitsresistente Sporen, sowie begrenzte Zelldifferenzierung, wie zum Beispiel die stickstofffixierenden Heterozysten bei den Cyanobakterien und die luftmyzelbildenden Sporen bei den Streptomyzeten, gehören ebenso zu den Überlebensstrategien von Bakterien. Innerhalb der Klasse der Deltaproteobakterien finden sich in der Ordnung Myxococcales Bakterienarten, die eine ganz besonders faszinierende Kombination an Eigenschaften besitzen. Sie alle sind in der Lage unter Verwendung von zwei unterschiedlichen Fortbewegungsmaschinerien auf festen Oberflächen in koordinierten Schwärmen vorwärtszugleiten und neben einigen Arten welche Cellulose verdauen können ernähren sie sich von der „Jagd“ auf andere Mikroorganismen. Dazu überschwärmen sie deren Kolonien und verdauen jene mit Hilfe hydrolytischer Enzyme. Zudem finden sich unter den Myxobakterien Produzenten einer Vielfalt von Naturstoffen. Berühmt sind sie jedoch vor allem für ihre Art und Weise Dauerformen zu bilden: Gehen die verfügbaren Nährstoffe, insbesondere Aminosäuren für die Proteinbiosynthese, zur Neige, so schwärmen die einzelnen Individuen einer Kolonie in Richtung von Aggregationszentren in denen nach und nach „Fruchtkörper“ genannte Gebilde entstehen. Diese sind von einer gallertartigen Schutzschicht umhüllt, mit Sporen gefüllt und weisen eine Höhe von bis zu 100 µm auf. In Abhängigkeit von der Art haben diese eine einfache hügelartige, bis hin zu einer sehr komplexen, baumförmigen Gestalt. Verständlicherweise wird seitens der Myxobakterienforschung der Frage wie Myxobakterien diesen für Prokaryoten sehr

komplexen Prozess koordinieren große Aufmerksamkeit gewidmet. So erkannte man bereits Ende der 70er Jahre in Untersuchungen an dem Modellorganismus *M. xanthus*, dass bestimmte Gruppen von Mutanten, welche nicht mehr zur Fruchtkörperbildung und Sporenbildung in der Lage sind, diese Fähigkeiten wiedererlangen können, wenn man sie mit dem Wildtypzellen oder Mutanten einer anderen Gruppe mischt. Daraufhin wurde die Hypothese aufgestellt, dass zwischen den Zellen für den Entwicklungsprozess notwendige Signale ausgetauscht werden, die bei der komplementierten Mutante fehlen. Somit definierte man fünf (A-E) Gruppen von „bedingt sporulationsunfähigen Mutanten“, auch als „Komplementationsgruppen“ bezeichnet und benannte die dazugehörigen Signale als A-E Signale, unbeachtete dessen, ob es sich um eines oder mehrere Signale, um Proteine, Peptide, kleine Moleküle oder Regulatoren handelt, welche bei den entsprechenden Mutanten nicht mehr zur Geltung kommen.

Die vorliegende Arbeit beschäftigt sich mit speziellen Aspekten des sogenannten „E-Signals“ in *M. xanthus*. Mutanten mit einem Defekt in der Funktion dieses Signals sind nicht mehr in der Lage aus verzweigt-kettigen Aminosäuren wie Leucin die korrespondierenden, um ein C-Atom verkürzten, verzweigt-kettigen Carbonsäuren zu erzeugen. Da in *M. xanthus* diese wichtige Vorläuferverbindung für verzweigt-kettige Fettsäuren, Naturstoffe und Isoprenoide sind, ist nicht ersichtlich, welches der betroffenen Verbindungen wichtig für die Fruchtkörperbildung und Sporulation sind. Erste Antworten geben die Resultate aus der Publikation „Isoprenoids Are Essential for Fruiting Body Formation in *Myxococcus xanthus*“. Für jene Untersuchungen standen im Vorfeld Mutanten zur Verfügung, welche eine verminderte Fähigkeit hatten, aus Acetat und/oder verzweigt-kettigen Carbonsäuren den Isoprenoidvorläufer 3-Hydroxymethylglutaryl-Koenzym A (3-HMG-CoA) zu synthetisieren. Diese wurden mikroskopisch auf ihre Fähigkeit untersucht, zeitabhängig Fruchtkörper zu bilden und mit Hilfe der Gaschromatographie gekoppelt mit Massenspektrometrie (GC-MS) verzweigt-kettige Fettsäuren zu synthetisieren. Anschließend wurden diese Ergebnisse verglichen mit jenen, die man erhielt, als die Mutanten genetisch durch das Gen für das Schlüsselenzym HMG-CoA Synthase (*mvaS*) oder die Zugabe von Mevalonolacton, einem Isoprenoidvorläufer, komplementiert wurden. Aus jenen Experimenten ergab sich, dass die Sicherstellung der Isoprenoidbiosynthese eine wichtige Voraussetzung für die Fruchtkörperbildung ist. Allerdings ist diese im Wildtyp erheblich auf die 3-HMG-CoA Biosynthese aus verzweigt-kettigen Carbonsäuren angewiesen. Hier scheint die Aktivität der HMG-CoA

Synthese nicht auszureichen, um einen Verlust zu kompensieren. Erst das Einbringen einer zusätzlichen *mvaS* Kopie oder die Komplementation mit größeren Mengen von Mevalonolacton (1 mM) gleichen den Verlust an 3-HMG-CoA Synthese wieder aus.

Kann es also sein, dass der Phänotyp der E-Signal Mutanten eher auf eine Verminderung der Isoprenoidbiosynthese und weniger auf jene der verzweigtkettigen Lipide beruht, letzteres also lediglich ein Surrogat für ersteres darstellt? Im Kontext zu einer vorhergehenden Arbeit gibt die Publikation „A multifunctional enzyme is involved in a novel bacterial ether lipid biosynthesis pathway“ eine recht klare Antwort. Es konnte bereits vorher gezeigt werden, dass *M. xanthus* während der Fruchtkörperentwicklung Etherlipide mit verzweigtkettigen Alkyl- und Acylresten akkumuliert. Dazu gehören der Vinyether „VEPE“ (PE(P-i15:0/i15:0) (verwendete Nomenklatur gemäß „LIPID MAPS Lipid Classification System“, siehe [http://www.lipidmaps.org/data/classification/LM\\_classification\\_exp.php](http://www.lipidmaps.org/data/classification/LM_classification_exp.php)) und die Alkylether „AEPE“ (PE(O-i15:0/i15:0) sowie das Alkyldiacylglycerol „TG-1“ (TG(O-i15:0/i15:0/i15:0)). Alle getesteten Mutanten mit Defekten in dem Entwicklungsprogramm akkumulieren keine Etherlipide, sodass es sich bei Ihnen zunächst um Biomarker für die Fruchtkörperbildung handeln. Die Suche nach Biosynthesegenen für Etherlipide führte zu einem aus fünf Genen bestehenden Cluster (genannt *elbA-E* für ether lipid biosynthesis) in dem das Gen *elbD* für ein bis dato unbekanntes Multidomänenenzym kodiert. Wird dessen Transkription gestört, so kommt es zu einer sehr starken Abnahme der Etherlipidbiosynthese inklusive einem Totalverlust an der Synthese von TG-1. Der Entwicklungsphänotyp hingegen ist eher schwach, jedoch enthalten die Fruchtkörper keine keimungsfähigen Sporen. Genetische Komplementation mit *elbD* führt zu einer Wiederherstellung der Etherlipidbiosynthese und des Entwicklungsphänotyps sowie einer Zunahme von lebensfähigen Sporen. Analoge Untersuchungen an *Stigmatella aurantiaca*, einen nahen Verwandten von *M. xanthus*, bestätigten das Ergebnis hinsichtlich der Bedeutung von *elbD* für die Etherlipidbiosynthese. Außerdem wurden Gene mit einer starken Homologie zu *elbD* in allen bisher sequenzierten Genomen von Myxobakterien identifiziert. Ferner zeigte eine stichprobenartige Untersuchung an einer Reihe von anderen Myxobakterien, dass sie alle Etherlipide bilden. Weitere Untersuchungen beschäftigten sich mit der Funktionsweise von ElbD. Biochemische Tests an heterolog exprimierten und isoliertem ElbD bewiesen die Existenz einer Acyl-Carrier-Protein- und Acyl-CoA Synthetasedomäne. Phylogenetische Untersuchungen und *in-silico* Dockingexperimente

gaben deutlich Hinweise auf eine weitere Acylglycerolphosphat-Acyltransferase-Domäne, welche PE(0:0/i15:0) als Acylakzeptor verwendet. Dies stand zudem im Einklang mit der Beobachtung, dass eben jenes PE(0:0/i15:0) in *elbD* Mutanten während der Fruchtkörperbildung anstatt von TG-1 akkumulierte. Eine weitere Domäne, welche laut der Conserved Domain Database des National Centers of Bioinformatics Homologien zu Acyl-CoA-Reduktase-Domänen besitzt scheint in die Erzeugung von i15:0 Aldehyd involviert zu sein: Wildtypzellen erzeugen dieses, und nur dieses, langkettige Aldehyd, wobei *elbD* Mutanten diese Fähigkeit nicht mehr besitzen. Fasst man die Ergebnisse zusammen, so gelang es im Zuge der Untersuchungen das erste bakterielle Enzym zu identifizieren, welches in die Etherlipidbiosynthese involviert ist. Darüber hinaus kann man die *elbD* Mutante als erstes Beispiel ansehen, bei dem eine bestimmte Gruppe von verzweigt-kettigen Etherlipiden identifiziert wurde, die ganz oder teilweise ein wichtiges Signal für die Ausdifferenzierung von vegetativen Zellen in Sporen darstellen. Demgegenüber kann der viel stärkere Phänotyp der *esg* Mutanten auf die Verarmung an mehreren Substanzklassen (Isoprenoide, sekundäre Naturstoffe, verzweigt-kettige Lipide) in Verbindung gebracht werden und ist somit unspezifischer als der *elbD* Phänotyp.

Im Zuge der gesamten Arbeiten an der Etherlipidbiosynthese und deren Bedeutung für die Fruchtkörperbildung stellte die Analytik der beteiligten Lipide aus den entsprechenden Extrakten eine große Herausforderung dar. Lipide der gesamten Polaritätsbreite von Lysophospholipiden über Glycerophospholipiden und Glycerolipiden bis hinunter zu einzelnen Molekülspezies mussten an der einen oder anderen Stelle identifiziert und deren relatives Vorkommen in unterschiedlichen Proben bestimmt werden. Hierzu mussten alle zur Verfügung stehenden Methoden angewendet und deren Ergebnisse kombiniert werden, um spezifische Aussagen treffen zu können. Um dies in Zukunft zu vermeiden wurde im Rahmen des dritten Manuskriptes eine einzige Methode entwickelt, die gleichzeitig in der Lage ist, das gesamte bekannte Lipidom von Myxobakterien bis zu einzelnen Molekülspezies darzustellen. Hierfür wurden Lipidextrakte aus Kulturen verschiedener Mutanten von *M. xanthus* mit Hilfe einer C18 Säule für die Ultrahochleistungsflüssigkeitschromatographie (UPLC) unter Verwendung eines Wasser/Acetonitril/Isopropanol Gradienten aufgetrennt und die eluierenden Lipide mit Hilfe eines Ionenfallenmassenspektrometers nach Elektrosprayionisation (ESI-MS) analysiert. Aus den Fragmentspektren der Molekülionen wurde die Klassen der Lipide und aus den Integralen der extrahierten Einzelionenchromatogramme deren relative Häufigkeit

ermittelt. Insgesamt 99 Molekülspezies konnten Lipiden zugeordnet werden. Identifiziert wurden Glycerophosphoethanolamine, 1-(1Z-alkenyl),2-acylglycerophosphoethanolamine, Glycerophosphoglycerole, Ceramide, Ceramidinositolphosphate, Diacyl- und Triacylglycerole. In dem Extrakt der *elbD* Mutante war wie erwartet der Gehalt an 1-(1Z-alkenyl),2-acylglycerophosphoethanolaminen stark vermindert, in jenem einer  $\alpha$ -Hydroxylasemutante ( $\Delta 0191$  (*MXAN\_0191*)) fehlten wie erwartet  $\alpha$ -hydroxylierte Sphingolipide und eine solcher von einer Serin-Palmitoyl-CoA-Transferase (*spt* (*MXAN\_3748*)) ließen sich keinerlei Sphingolipide mehr nachweisen. Trotz der Vielzahl der Molekülspezies ließen sich die Resultate in 3D Streudiagrammen ohne weitere statistische Aufarbeitung darstellen, sodass auch relativ quantitative Unterschiede in einzelnen Molekülspezies und Lipidklassen zwischen den einzelnen Extrakten für den Betrachter sichtbar wurden. Es steht somit nun eine geeignete Methode zur Verfügung, die auch unterschwellige Verschiebungen im Lipidom von Mutanten zu Tage fördern kann, ohne dass mehr als eine Analyse herangezogen werden muss. Bei Verwendung eines geeigneten Versuchsdesigns sind quantitative Aussagen ebenfalls möglich. Eine tiefere molekularbiologische und metabolische Untersuchung der Lipidbiosynthese in Myxobakterien kann nun angegangen werden. Zudem steht das gesamte Lipidprofil von *M. xanthus* für Vergleiche zur Verfügung.

Alles in allem gelang es mit dieser Arbeit die molekulare Natur der *esg* Mutante zu konkretisieren. Die aus Leucin gewonnenen verzweigt-kettigen Carbonsäuren stellen Vorläufermoleküle sowohl für Isoprenoide und sekundäre Naturstoffe als auch für Lipide mit verzweigt-kettigen Fettsäuren, inklusiver der Etherlipide dar. Ein reichhaltiges Angebot an Isoprenoidvorläufermolekülen ist eine ausreichende Voraussetzung für die Fruchtkörperbildung. Die Etherlipide hingegen sind notwendig für die Differenzierung der Zellen in lebensfähige Sporen. Ferner spielt ein bisher unbekanntes Multidomänenenzym eine zentrale Rolle in der Etherlipidbiosynthese von Myxobakterien dar und ist somit auch das erste Beispiel für einen prokaryotspezifischen Etherlipidbiosyntheseweg. Weitere Untersuchungen wären vonnöten, um festzustellen, ob spezifische Isoprenoide oder Etherlipide Signalcharakter haben. Darüber hinaus steht nun die exakte Erforschung der Lipidbiosynthesewege in *M. xanthus* mit den bereits vorhandenen molekularbiologischen und mit der neu entwickelten Lipidomtechnik offen.

# 1 Introduction

## 1.1 About myxobacteria: unicellular prokaryotes with strong social traits

The world of the smallest living beings remained inaccessible to early natural scientist until the invention of the light microscope. It was Antoine Philips van Leeuwenhoek, driven by his interest in lens making, to be the first to describe single-celled organisms in one of his numerous letters published by the British Royal Society in the 17<sup>th</sup> century<sup>1,2</sup>. Those organisms became of significant interest as bacteria were identified as originators of human diseases like tuberculosis, anthrax, and cholera by Robert Koch<sup>3,4</sup>.

In 1892, the American mycologist and member of the Cryptogamic Laboratory of the Harvard University, Roland Thaxter, comprehensively described a harmless, but particularly intriguing order of bacteria named the “Myxobacteriaceae”<sup>5</sup>. For the first time, and with the acute eye of a skilled and talented natural scientist, he aptly recognized these intriguing species as “Schizomycetes”, as prokaryotes (though by mistake regarded as “plants”) were named these days. Using color plates of impressive richness of detail drawn from microscopic investigations, he precisely described nine myxobacterial species with all features for which myxobacteria are generally known today. This work was published in the *Botanical Gazette* in December 1892<sup>5</sup>. What he saw seemed to impress himself so much that he noted: “This life history (...) is so peculiar, (...) and is altogether so unique to the group of Schizomycetes, to which they should undoubtedly be referred, that their separation as a distinct order seems unavoidable”<sup>5</sup>.

What makes myxobacteria special among the variety of prokaryotes? One of the most striking features of the myxobacteria was what Thaxter encountered first when his attention was drawn to these organisms. It was something visible by the naked eye that he described as “... a bright orange-colored growth occurring upon decaying wood (...) somewhat highly organized (...) to consist of apparently amorphous material, without signs of hyphae and spores of any kind. Its general appearance and the general character of the substance which composed it suggested an immature condition of some myxomycete (...) which, when artificially cultivated, yielded immature conditions that rendered already its true nature apparent”<sup>5</sup>. This “form” or “cyst”, as Thaxter named it, is known today as “fruiting body”<sup>6</sup>, a more or less structured, macroscopically visible, multicellular construction occupied by thousands of heat and drought resistant spores. **Figure 1.1** panel

**a** and **b** show original drawings of fruiting bodies by Thaxter at various stages from *Chondromyces crocatus* (**Figure 1.1 a**) and *Myxococcus rubescens* (**Figure 1.1 b**). At a first glance, these structures somewhat resemble the fruiting bodies of the eukaryotic, thus completely unrelated, slime molds. The close commonality of the myxobacterial fruiting bodies to those of the myxomycetes led to the misidentification of *Chondromyces crocatus* as a fungus before<sup>5,7</sup>. These fruiting bodies are formed by the individual vegetative rod-shaped cells (as exemplarily depicted in **Figure 1.1 c-g**) in a process known as “developmental process” or “fruiting body formation” already described in detail by Thaxter. The colors and structures of those fruiting bodies are used to describe individual taxonomic species and reach from simple “mounds” to complex “tree-like” structures with a vertical “stalk” and “branches” ending in rounded “cyst” which then contain, densely packed, mature spores referred to as “reproductive bodies”<sup>6,8,9</sup>.

**Figure 1.1 | Phenotypical characterization of myxobacteria back then and today**

Historical drawings from Thaxter (**a** and **b**) illustrating his observations by light microscopy and more recent images obtained by scanning electron microscopy (SEM) (**c-j**) from *Chondromyces crocatus* (**a/c-g**), *Myxococcus rubescens* (**b**) and *Myxococcus xanthus* (**h-j**) strains. Images **c-g** show different consecutive stages of fruiting body formation with a bulb formed first (**c**) which is gradually uplifted by a rising stalk (**d** and **e**) and finally separates into a couple of mature sporangia separated from the stalk by pedicels (**f**). The stalks as well as the pedicels are made of rods aligned in a parallel way (white arrow, **g**). **b**: Individual, slender, rod shaped vegetative cells as well as the sphere-shaped mature spores were well depicted by Thaxter (**39-41**) and identical to what a modern researcher perceives when investigating *Myxococcus* strains under a contemporary light microscope. Side view (**38**) and top view (**37**) of a mature fruiting body in its simple, mound-like form as characteristic of those from *Myxococcus* sp. surrounded by peripheral rods. **h**: A similar view acquired by SEM with peripheral rods visible in the background and the sphere-shaped spores that form the majority of the fruiting body. Images **i** and **j** are higher magnifications of vegetative rods and the spores visible in a fissure of a fruiting body. Note the extracellular fibrils surrounding the cells in **i**. Photo credits (each with permission): **a** and **b**: Thaxter<sup>5</sup> (Courtesy of JSTOR); **c-g**: Grilione and Pangborn<sup>8</sup>; **h**: O'Connor and Zusman<sup>10</sup>; **i**: Kearns and Shimkets<sup>11</sup>; **j**: Licking *et al.*<sup>12</sup>.

### 1.1.1 Taxonomy and properties of myxobacteria

Although Thaxter described myxobacteria as “plants”, to which Schizomycetes were assigned in those days, myxobacteria are Gram-negative, rod-shaped prokaryotes belonging to the genus myxococcales, an order of the  $\delta$ -subdivision of the proteobacteria, and are further subdivided into the three suborders Cystobacterineae, Sorangiineae and Nanocystaceae with an increasing number of families and species described as research progresses<sup>13</sup>. In general, myxobacteria can be isolated from, preferably pH neutral, soil samples all over the world with up to 450,000 individual cells per gram of soil. An extensive study, published in 2000, comprising 64 sample series with a total number of 1398 individual, globally collected samples, found only 9% free of myxobacteria<sup>14</sup>. Within a single soil sample, myxobacteria can account for between 0.4 - 4.5% of the bacterial community based on 16s rDNA gene sequencing<sup>15</sup>. As most myxobacteria are mesophilic, their highest variety of species occurs in the tropical climate, but psychrophilic (genera *Polyangium* and *Nannocystis*<sup>16</sup>), halo tolerant and halophilic (genera *Haliangium*<sup>17</sup>, *Enhygromyxa*<sup>18</sup>, *Plesiocystis*<sup>19</sup>) and microaerophilic (genus *Anaeromyxobacter*<sup>20</sup>) species were also isolated from Antarctic soil, marine coastal sediments and anaerobic environments respectively.

### 1.1.2 A huge genome for a unique lifestyle

The rather complex lifestyle of myxobacteria is also reflected in the size of their genomes. Several myxobacterial genomes were sequenced and that of *Sorangium cellulosum* So0157-2 exhibits with 14.78 Mb in size and an estimated number of 10,503 genes the largest genome of a prokaryote sequenced so far<sup>21</sup>. That is even bigger than the one of the eukaryotic yeasts from the genus *Saccharomyces* whose genome sizes range from 10-13 Mb<sup>22</sup>. The best studied myxobacterium *Myxococcus xanthus* has with 9.14 Mb (strain DK1622) a genome of intermediate size among the myxobacteria<sup>23</sup>. Interestingly, the species from the genus *Anaeromyxobacter* do only bear genomes of about 5 Mb<sup>24</sup> in size which is similar to *E. coli*<sup>25</sup>. Unlike all other known myxobacteria, *Anaeromyxobacter* do not form fruiting bodies which may indicate that the developmental process requires a large genome<sup>24</sup>.

With respect to the abundance of certain genes there are two unique features that distinguish myxobacteria from other prokaryotes: a large number of gene clusters

dedicated to the biosynthesis of secondary metabolites<sup>26</sup> and an unusual number of genes encode proteins which are involved in regulatory pathways<sup>23,27,28</sup>.

In general, myxobacteria were found to be potent producers of secondary metabolites quite early and more than 100 different basic structures with about 500 structural variants have been isolated since then<sup>29</sup>. A number of biological activities including inhibition of the respiratory chain (e.g.  $\beta$ -methoxyacrylates like myxothiazol, melithiazol and cyrmenins), antibiosis (e.g. myxovirescin) and cytotoxicity (e.g. tubulysins, chivosazols, epothilons)<sup>26,30,31</sup> were determined for some of these substances. The microtubule-stabilizing macrolactone epothilon has become the first and so far only myxobacterial natural product in clinical use against taxol-resistant breast tumor<sup>32</sup>. Most natural products from myxobacteria, for which data about their biosynthesis are available, have been identified as products of hybrids of non-ribosomal peptide synthetases (NRPS) and polyketide synthases (PKS), very often additionally modified by glycosylation, oxygenation, methylation etc<sup>29</sup>.

The genome of *M. xanthus* encodes 18 putative NRPS/PKS gene clusters<sup>26</sup> being potentially involved in the biosynthesis of secondary metabolites, which represent about 8.6% of the whole genome. This is considerably more than in *Streptomyces coelicolor* (4.5%)<sup>33</sup> and *Streptomyces avermitilis* (6.6%)<sup>34,35</sup>, two actinomycetes which are likewise well-known for being rich sources of natural products. However, under standard laboratory conditions, only five compound classes (the antibiotic myxovirescins, the myxalamids, myxochromides, the myxochelin siderophores and the DKxanthene pigments) are found in cell culture extracts<sup>36</sup>, even though almost all NRPS/PKS enzymes are detectable in transcriptomic and proteomic samples<sup>37,38</sup>. Finally, three more substances, myxoprincomide and two other entities with unknown structures, designated as c844 and c329, were identified after comparison of wild type and mutant extracts by means of ultra performance liquid chromatography coupled with mass spectrometry (UPLC-MS) and principal component analysis (PCA) of the resulting spectra<sup>39</sup>. Consequently, those biosynthetic genes are expressed and the resulting enzymes are active and do not represent “genetic waste”<sup>39</sup>. In addition to this, liquid chromatography coupled with mass spectrometry (LC-MS) based screening of 98 *M. xanthus* strains, isolated from all over the world, revealed that some of them produce other known secondary metabolites such as cittelin A and althiomycin<sup>36</sup>. The exact physiological and ecological meanings of the secondary metabolites are still largely unknown. With respect to its life cycle the

DKxanthenes are of significance for spore formation in *M. xanthus*. Mutants not producing DKxanthenes are defective in spore formation and act in the same way when pure substance is supplemented<sup>40</sup>.

Apart from a remarkably high density of genes involved in secondary metabolism, those encoding regulatory proteins are of high abundance in myxobacterial genomes. Many of them belong to the group of eukaryotic-like protein kinases (ELKs)<sup>27,41</sup>. These enzymes catalyze the reversible phosphorylation of proteins in order to modify their activity and are important elements of eukaryotic signaling systems such as neuronal G protein-coupled receptor (GPCR) mediated signal transduction or hormone dependent mitogen activation<sup>42,43</sup>. In myxobacterial genomes, their abundance increases exponentially with genome size. As a result, in *Sorangium cellulosum* and *Plesiocystis pacifica* their density, determined by number of kinases per thousand of coding sequences, is even higher than that of eukaryotes like mice, fruit flies and sea urchins<sup>27</sup>. In total, there are 99 ELKs present in *M. xanthus* and 317 in *S. cellulosum*. It seems as if the myxobacteria acquired and accumulated this kind of signal transmission and regulation systems to enable multicellular behavior, a hypothesis that is in accordance with a similar high density of ELKs in other prokaryotes with comparably complex lifestyles, such as of phyla actinobacteria, cyanobacteria and Chloroflexi. The typically one- and two-component signal transduction systems are also present in myxobacteria. However, they are rather underrepresented in myxobacterial genomes compared to those of other bacteria<sup>27</sup>. In short, most myxobacteria possess the largest genomes among known prokaryotes which feature an unusually high number of genes encoding regulatory proteins and those involved in the biosynthesis of natural products.

## **1.2 Features of *Myxococcus xanthus*: the favorite among the lab strains**

The aforementioned *Myxococcus xanthus* (family: Myxococcaceae, suborder: Cystobacterineae), the well-known model organism used for most molecular genetic studies, is also the central subject of investigation for the studies of this thesis. Its individual cells are slender rods with tapered ends, somewhat flexible, up to 10 µm in length with a diameter of up to 1 µm (see Thaxter's drawing in **Figure 1.1 b** and SEM image **i**)<sup>44</sup>. They produce extensive extracellular matrix with fibrils consisting of polysaccharides and proteins in which the whole colony is embedded when grown on a solid surface. *M. xanthus* is motile and, like most myxobacteria, feeds on other

microorganisms including bacteria and unicellular fungi by collectively swarming about and killing and digesting them using secreted lytic enzymes. This “hunting” behavior resembles the “wolf-pack” strategy of some carnivorous living animals<sup>45</sup>.

The fruiting bodies formed in response to unfavorable conditions (see **Figure 1.1 h** and **j**), especially nutrient deprivation, are rather simple, mound-like structures, coated with a gelatinous matter in contrast to the highly complex and impressive tree-like fruiting bodies formed by *Chondromyces* species (see **Figure 1.1 a** and **c-g**). This process has been partially deciphered by researchers up to date. **Chapter 1.3.1** outlines those findings in more detail. Fruiting body formation, however, cannot transpire without the cells motility.

### **1.2.1 Moving forward: motility of *M. xanthus***

As mentioned before, all myxobacteria are motile, which means that they can glide on solid surfaces along their length axis. For *M. xanthus*, the speed of progressing individual cells ranges from 1-20  $\mu\text{m}/\text{min}$  and, as a distinctive feature, they reverse directions once every 2-8 minutes depending on the conditions by swapping the leading and lagging cell pole<sup>46,47</sup>. They move in groups in an organized, collective manner. The microscopic image **a** in **Figure 1.2** shows the resulting locomotion patterns. They form “streams” in which cells follow slime trails secreted by their forerunners, “ripples” indicating a high reversal frequency of the individual cells (not shown) and “aggregates” leading to “mounds”, originating from a reduced reversal frequency of moving cells. Individual cells can also leave the edge of colonies and roam on their own. Macroscopically, this behavior results in a starburst-like growth pattern (see **Figure 1.2 b**)<sup>48-50</sup>.

Myxobacteria cannot move freely through liquid media and do not use flagella, but possess two different motility systems that work synergistically: The so-called “S”- (for social) and “A”- (for adventurous motility) motility systems. Those terms were coined as a result of observations made with mutants that show defects in either system<sup>51,52</sup>. The S-motility is required for coordinated group movements and the A-motility system is required for individual cells to move independently off the colony. Both systems use their own, genetically mostly independent, “engines”.

### **1.2.2 Type IV pili and S-motility: climbing forward horizontally**

S-motility, also referred to as “twitching” motility, is based on the utilization of Type IV pili, a homopolymeric filamentous protein emerging from one pole of the cell towards the

direction of movement<sup>53</sup>. The atomic force microscopy image in **Figure 1.2 c** visualizes those pili emanating from swarming *M. xanthus* individuals<sup>54</sup>. Their cell-averted ends attach to either the fibril network surrounding the bacteria in a colony or directly to the extracellular matrix of another cell and pull the cells together by retraction whereat the pilus is being simultaneously disassembled at the inner membrane<sup>55,56</sup>. By this means, the cells assist each other to move by providing the necessary anchor points for the retraction force. This perspective is supported by observations that S-motility is strongly impaired or absent not only when genes encoding elements of the pilus assembly are mutated but also when fibril or extracellular matrix formation is hampered<sup>57,58</sup>. Apart from myxobacteria, genes encoding proteins for the Type IV pili machinery are conserved in several other gliding bacteria like *Pseudomonas aeruginosa*, *Neisseria gonorrhoeae*, *Neisseria meningitidis*, *Synechocystis sp.* and the function of their protein products is partly known. By combining these findings, a working model for the molecular mode of action of the pilus apparatus has been constructed (see **Figure 1.2 d**)<sup>59,60</sup>.

### Figure 1.2 | Motility motors in *Myxococcus xanthus*

**a:** Still picture of a phase contrast microscopic time-lapse video. Single cells are able to leave the colony leaving a slime trail on which following cells preferably travel. Collectively swarming cells form rafts in which they are closely aligned abreast. When swarms of cells collide, they form mounds. **b:** Macroscopic swarming pattern of a *M. xanthus* colony after a few days of growth on nutrient agar. The colony adopts a radial pattern with an irregular edge and is rather flat. **c:** Image taken by atomic force microscopy. Arrows point on the clearly visible polar Type IV pili that confer S-motility to *M. xanthus*. **d:** Contemporary working model on how Type IV pili work on a molecular level. For details see text. **e:** Transmission electron microscopic images of the polar cell area unveiled ring-shaped nozzles with an inner diameter of about 6.5 nm and a total diameter of about 14 nm, resembling a very similar structure previously described for Cyanobacteria. **f:** Ribbons of mucilage emanate from the posterior cell pole with the same speed as the cell moves ahead, an observation leading to the slime secretion model (see text). **g:** Shock frozen and dried motile *M. xanthus* cells exhibit a helical band (arrows indicate nodes where the band intersects) that spans the entire length of the cell. **h:** Discovery of protein clusters that remain stationary during cell movement (note: red dots are fluorescently labeled proteins associated with the helix; protein clusters remaining stationary at the basal side are connected with a straight line) (**i**) led to the focal adhesion model (see text). **j:** The helical rotor model proposes rearwards moving surface waves provoked by motor proteins that move along the helical cytoskeletal filament. Photo credits (each with permission): **a:** Wu *et al.*<sup>48</sup>; **b:** Jelsbak and Kaiser<sup>61</sup>; **c:** Li *et al.*<sup>54</sup>; **d:** reproduced from Kaiser; **e** and **f:** Wolgemuth *et al.*<sup>62</sup>; **g:** Lünsdorf and Schairer<sup>63</sup>; **h-j:** Nan and Zusman<sup>64</sup>.

According to this model, the pilus is made up of polymerized PilA monomers after their procession by PilD in the inner membrane. On the whole, the pilus spans the cytoplasm and penetrates the outer membrane through a pore made up of PilQ secret in monomers. After attaching to extracellular material or the surface of other cells, the pilus is retracted by the actions of PilT, an ATP-dependent motor protein, exerting the necessary force to drag the cell forward while the pilus is disassembled in the inner membrane simultaneously. Another motor protein, PilB, is responsible for the extension of the pilus. With a diameter of about 10 nm, it is very thin. As a result, the load force of the extending pilus is too weak to push the cell backwards<sup>53</sup>.

In summary, the S-motility engine provides a basis for the coordinated propagation of a myxobacterial cell swarm. However, its' single cells cannot move as individuals because of missing extracellular matrix outside the colony so that a different kind of engine is required.

### **1.2.3 The secret of gliding motility: of microbial rocket engines and snakes**

A-motility, referred to as “gliding” motility, a phenomenon also observed from cyanobacteria, flavobacteria and mycoplasmas, excels in movement of cells without the help of pili, flagella or any other visible motor structures outside the cells' envelope or the change of their morphology<sup>65</sup>. This made the investigations of the underlying mechanisms difficult. To date there are three, partially competing, models about how gliding motility exactly works for myxobacteria. Even so, some important elements involved in myxobacterial gliding motility engine were recently unveiled.

The production of slime is a prerequisite for gliding in myxobacteria<sup>62</sup>. The distal poles of the bacteria exhibit nozzles assumedly involved in slime secretion (**Figure 1.2 e-f**). The force produced by the secretion and hydration of the polyelectrolyte chains are considered to produce the sufficient thrust that pushes the cell forward in a rocket-engine-like manner. Backed up by a mathematical model this hypothesis led to the “slime secretion model”<sup>62,64</sup>.

Later, scanning electron microscopical observations of freeze-dried *M. xanthus* cells revealed dynamic, helical bands spanning the interior site of the cells' envelopes along their entire length, described as a “closed band-shaped continuum which is twisted along the longitudinal axis of the cell”<sup>63</sup>. Those structures were also discovered in other bacterial species that translocate by gliding like *Flavobacterium johnsoniae* and *Flexibacter*

*filiformis* (**Figure 1.2 g**). Moreover, these filaments are absent in cells, immobilized by poisoning or genetic defects. Further time-laps fluorescence microscopy video analysis of cells featuring fluorescently labeled proteins associated with this structure disclosed its clockwise rotation when the cells glide with a pitch and speed consistent with the progress of the cell<sup>66,67</sup>. When the cell reverses, the helix turns to the opposite direction<sup>68</sup>. Several proteins were identified that form “traffic-jam” like clusters at the basis of the cell along this helical ribbon (**Figure 1.2 h**). While the cell moves forward, those protein clusters are being assembled at the anterior cell pole and remain virtually immobile while staying attached to the rotating helix until they reach the posterior cell pole to get disassembled again<sup>64</sup>. But how can these proteins cause a propulsive force? About 40 genes are involved in gliding motility, and several proteins being associated with the protein motor clusters or the intracellular helix structure were identified<sup>69</sup>. The helix as a whole is associated with the actin-like structural homolog MreB, an actin-like homolog, which itself forms helical filaments, represents an element of the myxobacterial cytoskeleton and is furthermore vital for the integrity of the gliding machinery. MreB is associated with the myosin domain containing protein AglZ<sup>67</sup>. Together with AgmU, a central interaction partner of proteins involved in gliding motility, it is the first observed constituent of the motor protein cluster that moves along the helical structures. Homologues of MotA/B, *E. coli* stator flagella proteins<sup>70,71</sup> and as such important elements for the production of thrusting force, designated AglX/AglV and AglR/AglS/AglQ respectively, were also identified as part of the gliding engine<sup>68,72</sup>. They may be responsible for the production of the required force. Those motor proteins also interact with AgmU<sup>66</sup> and likewise MotAB homologues, their source of energy is dependent on the proton gradient across the cytoplasmic membrane, also referred to the “proton motive force”<sup>68</sup>.

Although this information may not be sufficient to fully assign functions to the potentially involved proteins, two working models for the mechanism of gliding were suggested. The “focal adhesion model”<sup>73</sup> (**Figure 1.2 i**) suggests that adhesion complexes connecting the substratum with the cell are being transported from the front to the back of the cell by the movement of the helical structure in order to mediate the cell movement similar to the tracks of a tank or tractor crawler. However, as there seem to be no such cell surface associated adhesion proteins present in *M. xanthus*, the competing “helical rotor model”<sup>64,74</sup> proposes that proteins riding as cargo on the helical track accumulate when reaching the ventral side of the cell causing transverse protrusion along the basal surface.

When propagated from the front to the back by the action of the turning helix, they cause driving force mediated by the secreted slime sticking to the substrate just like the waves of muscle contractions cause propulsion in a snail's body (**Figure 1.2 j**). The mechanisms underlying the myxobacteria's ability to glide again reveal the genetic and mechanistic versatility of the organisms. But the ability to move is only an easily conceivable prerequisite to what makes these bacteria master builders among the prokaryotes: fruiting body formation.

### **1.3 Intercellular communication during fruiting body formation: from complementation groups over genetic loci and proteins to small molecules**

#### **1.3.1 The process of fruiting body formation in *M. xanthus***

As already mentioned, most studies on the environmental prerequisites, the process and the molecular basis such as regulation, intra- and intercellular communication, were carried out on *M. xanthus*<sup>44</sup>. The reason for this is probably its relatively easy and reliable handling in a laboratory environment compared to other myxobacteria. If the conditions, especially temperature, media composition and cell density, are well-defined, the process in the order of the single events is temporally highly reproducible<sup>9,75</sup>. **Figure 1.3 a-c** depicts this process on a macroscopic (**a**) microscopic (**b**) and schematic (**c**) level respectively. Within 72 h, disordered, vegetative cells on a solid surface form the typical mound-shaped, spore filled fruiting bodies. Those fruiting bodies are made of up to  $10^5$  cells being transformed to round, thick-coated, refractive, metabolically quiescent spores, which are able to form a whole colony again when environmental conditions become favorable. Most interestingly, during the process of fruiting body formation, three types of cells emerge. About 10 % of all cells become the actual spores, another 10% stay rod like unable to fruit and are called “vegetative rods”<sup>10</sup>, and 80% of the remaining cells undergo a programmed cell death (PCD)<sup>76</sup>, thus sacrificing themselves to provide sufficient resources for the developmental process. The exact ratio between these cell populations is however strain specific<sup>10</sup>.

**Figure 1.3 | Fruiting body formation in *M. xanthus***

**a:** Series of binocular loupe view of  $\sim 2.5 \times 10^7$  *M. xanthus* cells on a starvation agar during the process of starvation induced fruiting body formation. Black bar is 500  $\mu\text{m}$ . **b:** Scanning electron microscopy images of the origination of a single fruiting body in a submersed culture. White bar is 10  $\mu\text{m}$ . **c:** Schematic view of cell differentiation during development. Motile cells start to swarm away from the colony but limited food supply causes the initiation of the developmental program leading to the formation of aggregation centers first (6 h) that successively transform into mounds (12 h) which are the basis of the fruiting bodies (24 h) that gain increasing optical density while vegetative cells transform into spores (72 h and ongoing). Triangles indicate points when A- and S- signal come into effect. For details see text. Pictures **a** are taken from preliminary studies for publication shown in **Chapter 6.2** Pictures **b** are taken from Kuner and Kaiser<sup>9</sup>. Scheme **c** was created from references quoted in **Chapter 1.3**.

### 1.3.2 The exigency of intercellular communication as the prerequisite for the developmental program gradually unraveled: how do *M. xanthus* cells “talk” to each other?

As there is an obvious need for cell-cell communication between the individual cells, one major interest of researchers in the field of myxobacteria has been to find, define and identify distinct signals that mediate the spatial and temporal coordinative behavior of the cells during the course of the well-defined process of fruiting body formation. The

outcomes and the degree of precision of the research done on this topic were strongly determined by the availability of methods in the past. Most research was performed utilizing molecular genetic methods which focus on the requirement and temporal expression of genes with respect to an observable phenotype<sup>77</sup>. The exact functions of the gene products and the involvement of small molecules as “signals” are a rather new subject. Investigations anent the A-, C-, and particularly E- group of conditionally non-sporulating mutants<sup>78,79</sup>(see next chapter) led to the non-exhaustive identification of individual proteins and, to some extent, their functions that are central elements at certain stages of fruiting body formation. However, no small molecules with a distinctive chemical structure and a defined mode of action acting as signals were identified to date. At least, for the myxobacterium *Stigmatella aurantiaca*, a close relative of *M. xanthus*, a substance named stigmolone was isolated, its structure verified, and a clear dose-response curve exhibited its function as a pheromone<sup>80,81</sup>. Still, a molecular target responsible for this biological activity is unknown. The following paragraphs summarize the present knowledge about genes, proteins and small molecules that are somehow involved or at least associated with the intercellular communication during fruiting body formation.

### **1.3.3 The long-lasting struggle: from complementation groups over genetic loci and proteins to small molecules**

In a first step after the application of random mutagenesis on *M. xanthus* cells and the investigation of their resulting phenotypes with respect to the developmental process, it was possible to determine several groups of “conditionally non-sporulating mutants” subdivided into groups A-D (later named *asg*, *bsg*, *csg* and *dsg* mutants respectively)<sup>78</sup>. In addition to the four initially described complementation groups, a fifth (designated as *esg*) group of conditionally non-sporulating mutants with one relevant genetic locus was identified<sup>79</sup>. These mutants feature defects at various points of fruiting body formation and sporulation, but can regain their ability to sporulate at least to some extent when mixed with either wild type cells or mutant cells that belong to another complementation group, without transfer of genetic material<sup>78</sup>. Those properties indicate the transfer of somewhat signaling molecule(s), which are missing or have become ineffective within the respective complementation group.

Transposon mutagenesis using Tn5::kan constructs<sup>82</sup> and eventually the use of transposable promoter probes<sup>83</sup> helped to identify the location as well as the moment of the expression

of genetic elements in the developmental process<sup>84</sup>. As a result, it has been possible to assign distinctive genetic loci which are no longer active after starvation induced morphogenesis in the respective complementation groups. Finally, molecular cloning and sequencing disclose for what kind of protein they encode<sup>85</sup>. These experiments indicated that each complementation group bears not only one but several distinctive mutations in different genetic loci<sup>86</sup>. For example, for the *asg* mutants three loci (*asgA-asgC*) were initially described<sup>87</sup> and two other loci (*asgD* and *asgE*)<sup>88</sup> later.

#### **1.3.4 The A-Signal: amino acids that make the difference**

Mutants belonging to the *asg* group show an arrest within the first hours of the process of aggregation and fruiting body formation resulting in loose aggregates without myxospores<sup>89</sup>. Those mutants cannot only be rescued by mixing with wild type cells but interestingly also by the addition of cell culture supernatant of developing wild type cells. Two *M. xanthus* proteins with 27 and 10 kD in size respectively were found to be a heat-labile part of this signal<sup>90</sup>. These proteins in turn seem to generate a set of six different amino acids (Tyr, Phe, Trp, Leu, Ile) and small peptides consisting thereof by proteolytic activity. These amino acids are all also active by themselves and represent a heat-stable component of the A-signal<sup>90</sup>. The mutations behind the *asg* group were however not associated with those proteases. Instead, they were all within genes associated with signal transduction. Genes *asgA* and *asgD* encode for hybrid histidine kinases<sup>90,91</sup>, *asgB* for a DNA binding protein<sup>90</sup>, *asgC* for a sigma factor and *asgE* for a membrane bound amidohydrolase<sup>88</sup> together being proposed as a phosphorelay system that responds to the A-signal molecules in a concentration depended manner<sup>92</sup> so that the A-signal is regarded as a true quorum sensing system in myxobacteria<sup>93</sup>.

#### **1.3.5 The B-Signal: the arcane protease**

For this group of conditionally non-sporulating mutants, only one gene defect was identified located in *bsgA* that encodes for an ATP-dependent LonD-like protease<sup>94</sup>. Mutations within this gene cause an early block in the developmental program resulting in mutants that produce less than 0.01% spores compared to the wild type<sup>78,89</sup>. However, it was not possible to assign specific signaling molecules to this group to date so that the nature of this signal remains elusive.

### 1.3.6 The C-signal: enzyme or not enzyme?

The developmental program of C-signal mutants is disturbed from 6 h after induction so that mutants fail to ripple and only form loose mounds until 24 h without sporulating and those aggregates start to disseminate again afterwards<sup>95</sup>. This phenotype is caused by a mutation in the *csgA* gene<sup>96</sup>. Two forms of this protein exist, named p17 and p25, with the apparent molecular mass of 17.7 and 25.5 kD respectively<sup>97</sup>. The former is a C-terminal fragment derived from the latter by proteolytic cleavage, which represents the full-length translation product of *csgA*. This cleavage is performed by the secretable protease PopC that is in turn usually kept inactive by PopD under vegetative conditions<sup>98</sup>. Protein p17 is found on the cell surface and able to rescue *csgA* mutants even when added to a starving culture as a recombinant protein<sup>97</sup>. The p25 CsgA protein belongs to the short-chain dehydrogenase (SCAD) like proteins. Mutagenesis experiments proved that the C-Signal activity of recombinant CsgA is abolished when either the NAD<sup>+</sup> binding motive or a motive known to be essential for SCAD activity is altered<sup>99</sup>, which argues for the catalytic processing of another molecule by CsgA. However, the p17 form of CsgA lacks the N-terminal NAD<sup>+</sup> binding motive<sup>97</sup> and still possesses the full C-signal activity. This p17 form can be isolated from membrane fractions of developing *M. xanthus* cell<sup>100</sup>. As neither the specific receptor of p17 nor the substrate of p25 has been determined until now, the exact molecular mechanisms of C-signaling remain unclear. Interestingly, another SCAD-like enzyme encoding gene, designated as *socA*, was found to substitute for *csgA* defects when strongly overexpressed<sup>101</sup>. Recombinantly produced SocA is able to oxidize lysophosphatidylethanolamine *in-vitro*. It is most effective on PE(16:1 $\omega$ 5c/0:0), a lysophosphatidylethanolamine with the most abundant straight chain fatty acid in myxobacteria<sup>102</sup>, but the structure of the product remains elusive<sup>103</sup>.

### 1.3.7 D-Signal: mutants being too “slow” to aggregate

Mutants of the *dsg* group bear a mutation in *infC*, a gene encoding for an InfC-like protein, the essential ribosomally associated translation initiation factor<sup>104</sup> causing a growth defect on agar plates as well as an arrest in fruiting body formation and sporulation after 4 hours of induction. Mixing with wild type cells only restores sporulation to 10%<sup>105</sup> of the wild type level. By these observations, a perturbation of protein biosynthesis is held responsible for the perturbation of a normal development, and involvement of small molecule metabolites seems to be unlikely.

### 1.3.8 The branched-chain keto acid decarboxylase. lipids, secondary metabolites and the E-signal: one enzyme to rule them all

The E-group belongs to the latest discovered conditionally defective developmental mutants<sup>79</sup> and will be described in more detail as the E-signal is the superordinate topic of this thesis. An *esg* mutant aggregates but fails to form fruiting bodies and spores during the developmental program, shows less yellow pigmentation and a reduced adherence to hard surfaces. It was discovered that the *esg* phenotype is caused by a mutation in the E1 subunit of the branched-chain-2-oxo-acid dehydrogenase (BCKAD) complex<sup>106</sup> whereat they were consequently redefined as *bkd* mutants. The complex as a whole is central for the utilization of (for *M. xanthus* essential) branched-chain amino acids valine, leucine (**Figure 1.4, 1**) and isoleucine after their deamination and decarboxylation yielding the branched-chain acids isobutyrate-CoA, isovaleryl-CoA (**Figure 1.4, 2**) and 2-methylbuteryl-CoA respectively. The E1 subunit (encoded by genes *MXAN\_4564* and *MXAN\_4565*) is responsible for the decarboxylation of the branched-chain keto acids (**Figure 1.4, 2-oxo-isocaproate 3**) to the corresponding branched-chain acid. Those organic acids are not only the starter units of the branched-chain fatty acids (e.g. isopentadecanoic acid (i15:0)), which constitute up to 60% of all fatty acids in *M. xanthus*<sup>102</sup>, but are also incorporated into myxobacterial secondary metabolites like myxalamids<sup>107</sup>, myxothiazols<sup>108</sup> and even terpenoids like aurachin and geosmin<sup>109</sup> as well as the steroid cycloartenol found in *Stigmatella aurantiaca*<sup>110</sup>. Accordingly, fatty acid composition with respect to the ratio between branched-chain and even-chain fatty acids is strongly growth medium dependent and *bkd* mutants show a reduced capability to produce branched-chain fatty acids<sup>111</sup>. These findings emphasize the centrality of the BCKAD in the metabolism of *M. xanthus* and other myxobacteria, but strongly impede the exact assignment of individual metabolites to specific functions in the process of fruiting body formation.

Still, *bkd* mutants produce a considerable amount of iso-fatty acids<sup>111</sup>. The observation that acetate is being incorporated into iso-branched hydrocarbon moieties of fatty acids and secondary metabolites<sup>112</sup> in these mutants led to the discovery of the mevalonate dependent branched-chain acid biosynthetic pathway.

### 1.3.9 The mevalonate dependent pathway: connection between iso-branched compounds and isoprenoids in *M. xanthus*

The observation of BCKAD-independent formation of iso-branched compounds led to the identification of a biosynthetic pathway branching off from the mevalonate-dependent isoprenoid biosynthetic pathway (see **Figure 1.4**). The mevalonate synthase (encoded by the *mvaS* (MXAN\_4267) gene) is upregulated in *bkd* mutants, and a *bkd, mvaS* double mutant exhibits a more severe phenotype concerning fruiting body formation, sporulation and the synthesis of iso-branched fatty acids<sup>55</sup> than a *bkd* single mutant. Like the *bkd* single mutant, the phenotypes double mutant can be simply rescued by the addition of isovaleric acid<sup>55,113</sup>. This alternative pathway is strongly induced during fruiting body formation and in *bkd* mutants, but plays an inferior role under vegetative conditions and if rich food supply is provided<sup>55</sup> (see also **Figure 2** in **Chapter 6.1**). The full pathway is depicted in **Figure 1.4**. In more detail, 3-hydroxymethylglutaryl-Coenzyme A (3-HMG-CoA, **Figure 1.4, 4**), which is provided by the action of the mevalonate synthase (MvaS), is dehydrated by the methylglutaconyl-CoA hydratase (LiuC, MXAN\_3757) to 3-methylglutaconyl-CoA (3-MG-CoA, **Figure 1.4, 5**), whereas LiuC can operate in both directions. A 3-Methylglutaconyl-CoA decarboxylase, which consists of two subunits AibA (MXAN\_4264) and AibB (MXAN\_4265), decarboxylates 3-MG-CoA to 3,3-dimethylacrylyl-CoA (DMAA-CoA, **Figure 1.4, 6**), which is further reduced to isovaleryl-CoA (IV-CoA, **Figure 1.4, 2**) by the action of the IV-CoA dehydrogenase AibC (MXAN\_4266). Conversely, the short-chain-CoA dehydrogenase LiuA (MXAN\_3760) can reverse these reactions together with the propionyl-CoA carboxyltransferase LiuB (MXAN\_3759) and the methylglutaconyl-CoA hydratase LiuC. The resulting 3-HMG-CoA enters isoprenoid metabolism after its reduction to mevalonic acid (**Figure 1.4, 7**).

The protein functions were first deduced from the activities of homologues and confirmed by gene inactivation, gene complementation as well as metabolic labeling experiments<sup>38,55</sup>. Additionally, the complete reaction cascade from 3-HMG-CoA to IV-CoA was completely reconstructed *in-vitro* using heterologously expressed LiuC, AibA, AibB and AibC<sup>114</sup>. Thus, the *bkd* mutant is affected in the synthesis of various kinds of branched-chain compounds, including isoprenoids, secondary metabolites and any lipid that contains an iso-branched fatty acid or a moiety derived thereof. The deficiencies are partly, but not sufficiently, compensated by the shunt pathway. The complex interactions in this pathway

further complicate a prediction about which particular metabolite(s) or group of metabolites may be responsible for the *esg* phenotype.

### 1.3.10 Ether lipids in myxobacteria: just a biomarker?

Glycerophospholipids with a vinyl or alkyl ether linked fatty acid derived alkyl chain (plasmalogens) were found in *Myxococcus fulvus*<sup>117</sup> and *Stigmatella aurantiaca*<sup>118</sup> and their exact structures and occurrence in *M. xanthus* DK1622 were recently studied in detail<sup>119,120</sup>. Ether lipids PE(P-i15:0/i15:0), PE(O-i15:0/i15:0), and TG(O-i15:0/i15:0/i15:0) (named TG-1) were identified (see **Figure 1.4** for the structures and the “LIPID MAPS Lipid Classification System” ([http://www.lipidmaps.org/data/classification/LM\\_classification\\_exp.php](http://www.lipidmaps.org/data/classification/LM_classification_exp.php)) for nomenclature of lipids in general<sup>121,122</sup>). Along with other triacylglycerols, they are specific biomarkers for cells that become spores in the process of starvation-induced fruiting body formation. Analogously, alkylglycerols were less abundant in *asg* and *csg* mutants that hardly sporulate. PE(P-i15:0/i15:0) and PE(O-i15:0/i15:0) also accumulate relative to PE(i15:0/i15:0), the most abundant glycerophospholipid in *M. xanthus*, when cells are starved, whereas PE(O-i15:0/i15:0) levels attain a maximum at 24 h after starvation-induced fruiting body formation. Additionally, and most notably, concerning the search for signal molecules, TG-1 is able to rescue a *bkd*, *mvaS* double mutant to a similar extent as i15:0 fatty acid for both, fruiting body formation and sporulation<sup>119</sup>.

## 1.4 Aims of this work

Plenty of effort was invested in the description and investigation of the basis of cell-cell communication necessary for the process of fruiting body formation in *M. xanthus* (see **Chapter 1.3**). Most findings are related to genes, fewer on proteins and hardly any to small molecules involved in this process, with the pheromone stigmatolone<sup>80,81</sup> produced by *Stigmatella aurantiaca* being the only molecule with a proven signaling function. The DKxanthenes produced by *M. xanthus* are essential for sporulation, but for which reasons remains elusive<sup>123</sup>. The work done on the shunt pathway between isovalerate and mevalonate (**Chapter 1.3.9**) as well as the discovery of the iso-branched ether lipids that are somehow involved in the process of fruiting body formation and sporulation of *M. xanthus* (**Chapter 1.3.10**) provided excellent starting points for the discovery of further elements in the fascinating spectacle of fruiting body formation and disclosed continuative research questions. Mutants with an isoprenoid biosynthesis being separated from amino acid utilization have become available<sup>38</sup>. Those mutants could be used to elucidate the extent of the participation of isoprenoids and branched-chain compounds in fruiting body formation. Furthermore, the urgent question arose how *M. xanthus* synthesizes the ether lipids as only the well-studied mammalian pathway was known. Once biosynthetic genes are found, one can also call on respective mutants to study the ether lipids relevance for the developmental process.

Additionally, the discovery of the ether lipids and the already known highly complex fatty acid pattern<sup>115</sup> of the myxobacteria necessitated the development of new methods to further explore and display the pattern of the complex lipids as a whole. With a method in hands to track individual lipid molecular species, a researcher can further explore how myxobacteria adapt their lipid composition during the different stages of cell differentiation and may lead

to the identification of lipid signaling molecules and/or biomarkers for fruiting body formation.

In the end, one central question is floating around over investigations associated with *bkd* derived compounds: What exactly is the “E-signal”? A particular small molecule, like a hormone or pheromone? A more or less structural coherent group of small molecules? Or is the “E-signal phenotype” after all the result of a less specific multifactorial disorder, caused by the drastic changes in the metabolism of a *bkd* mutant? The herein presented research results are intended to contribute to this basic question as part of the general effort to understand how myxobacteria manage their developmental cell differentiation, a process unparalleled in the kingdom of prokaryotes.

## 3 Discussion

### 3.1 Isoprenoids in fruiting body formation and sporulation: how much isoprenoid is in the E-signal?

As described in **Chapter 1.3.9**, the mevalonate-dependent IV-CoA biosynthetic pathway provides a link between isoprenoid formation and that of iso-branched fatty acid derived compounds so that the majority of *bkd* associated developmental defects may be associated with either compound class. For example, the biosynthesis of isopentenyl pyrophosphate (IPP, **Figure 1.4, 8**) and dimethylallyldiphosphate (DMAPP, **Figure 1.4, 9**) from acetate units starting with acetoacetyl-CoA via 3-HMG-CoA (**Figure 1.4, 4**) may be insufficient under starvation conditions. This can result in a depletion of IPP derived primary metabolites, like quinones from the respiratory chain or bactoprenols for cell wall biosynthesis. This unspecific effect would disagree with the signaling-deficiency hypothesis (**Chapter 1.3.8**).

Reinvestigation of several readily available mutants<sup>38,55</sup> provided an answer to the question how much “isoprenoid is in the E-signal”. Especially the results from mutants HB002 (*Δbkd, liuC*) and HB015 (*Δbkd, MXAN\_4265 (aibB)*) that successfully uncouple IPP from iso-branched fatty acid biosynthesis are of great importance. As evident by **Figure 3** from **Chapter 6.1**, the addition of excess the IPP biosynthesis complementing mevalonolactone to these mutants is able to partially complement the developmental phenotype with respect to timing and appearance of fruiting bodies without increasing the relative amount of i15:0 fatty acids. This was used as a proxy for IV-CoA supply. Interestingly, genetic complementation by addition of an extra copy of the mevalonate synthase *mvaS* (HB019 and HB020) proved to be more efficient in all tested cases. Under these circumstances, a *bkd* mutant is now able to produce almost wild type levels of i15:0 (HB019) so that one can conclude that the upregulation of the *mvaS* expression in a *bkd* mutant (see **Figure 2 B** from **Chapter 6.1**) seems to be insufficient to compensate for the loss of leucine utilization, whereas the conversion of 3-HMG-CoA to IV-CoA is not a limiting factor. In summary, an adequate level of isoprenoids is essential and sufficient to achieve fruiting body formation with or without wild type levels of iso-branched compounds.

After all, this perspective neglects one decisive parameter: the number of viable spores. A mutant may form fruiting bodies much alike the wild type, but still be incompetent in the formation of heat and sonication resistant spores that germinate when subjected to a

permissive temperature and nutrient levels. This has been shown for a mutant impaired in the biosynthesis of DKxanthenes for example<sup>40</sup>. However, Ring *et al.*, though with other intentions, already addressed this question by determining the relative number of viable spores of the *Abkd, mvaS* (DK5624) double mutant in the presence of mevalonolactone and, amongst others, the neutral lipid tripalmitin (TG(16:0/16:0/16:0))<sup>119</sup>. Decomposition of this lipid only provides acetyl-CoA in the end, so that it is no use for the isoprenoid formation in *M. xanthus* via the IV-CoA dependent IPP formation (**Figure 1.4**). As expected, DK5624 produced only few (0.04%) spores and had a stronger phenotype than in **Figure 3 (Chapter 6.1)** as less mevalonolactone was used for complementation. Astonishingly, addition of tripalmitin restored the phenotype of DK5624<sup>119</sup> and increased the level of spores to 1% wild type level similar to the *mvaS* complementation in strain HB019/020. Those observations taken together may suggest that there is another *mvaS* independent, still undiscovered, pathway to IPP in *M. xanthus*. Nevertheless, a sufficient isoprenoid level does not allow wild-type level of viable spores. Consequently, it is likely that a compound with an iso-branched moiety is required for spore formation at some point of the process.

### **3.2 Isobranched ether lipids and E-signaling: are they the missing signal?**

Isovalerate and the fatty acid i15:0 derived thereof reconstitutes sporulation in DK5624 more effectively than any other tested compound. Their addition in excess to starvation media results in 40% and 30% spore formation relative to the wild type respectively. Synthetic TG-1 (TG(*O*-i5:0/i15:0/i15:0), see **Figure 1.4**) restores 25% of the spore formation in the same mutant<sup>119</sup>. Additionally, the cells seem to be attracted by this lipid as fruiting body formation preferentially took place around droplets of TG-1, phenomena that were absent when tripalmitin was used. These findings were recently confirmed in more detailed experiments, for which the dose-dependent ability of i15:0, TG-1, 16:0 and TG(i15:0/i15:0/i15:0) (the latter two served as controls) to restore the sporulation efficiency of a *Abkd, MXAN\_4265 (aibB)* mutant (LS1191) was established<sup>124</sup>. Both i15:0 and TG-1 rescued LS1191 in physiological concentrations, meaning that 1/3 of the molar amount of i15:0 and twice the amount of TG-1 compared to wild-type levels had 50% of maximum rescue capacity, whereas the other two lipids failed to do so. Again, i15:0 was more effective than TG-1, yet TG-1 stimulated the expression of the heretofore unknown developmental marker *MXAN\_2146*. Is then i15:0 the true precursor of the E-signal and not

the alkylglycerol TG-1? This conclusion seems natural, but the occurrence of TG-1 has to be discussed together with the appearance of lipid bodies in *M. xanthus* over the course of the developmental program.

When subjected to stress, to be more precise, antibiotics, anoxic conditions or nutrient deprivation, the cells start to form lipid bodies beginning from the cell poles<sup>120</sup>. Their size ranges from 50-500 nm in diameter and consist of glycerolipids including monoalkyl-diacyl- and alkylmonoacylglycerols and are surrounded by a monolayer of glycerophospholipids, mainly VEPE (PE(P-i15:0/i15:0)) and AEPE (PE(O-i15:0/i15:0)). The severer the stress, the more pronounced is lipid body formation. More importantly, these lipid bodies are only formed by cells that either undergo programmed cell death or sporulation and not by cells that become peripheral rods during the course of starvation induced fruiting body formation. In wild type cells, maximum lipid body production is observable at 24 h after initiation of the developmental program<sup>120</sup>. The most abundant lipids are alkylglycerolipids with TG-1 as the principal component. With ongoing transformation to resistant spores, lipid bodies disappear and quantities of glycerolipids resume wild type levels. In spite of this, methanolized spores retain high levels of *O*-i15:0-glycerol<sup>119</sup>.

Certain mutants (e.g. DK5608 (*csgA* (*MXAN\_1294*)) or DK5624 (*Abkd*, *mvaS*), which neither fruit nor sporulate, do not form lipid bodies and they produce only small amounts of glycerolipids<sup>120</sup>. The same is true for peripheral rods which seem to have lost the ability to perform fruiting body formation and sporulation. Additionally, mutants *asgA* (*MXAN\_2670*), *csgA* (*MXAN\_1294*), *fruA* (*MXAN\_3117*) accumulate vinyl ether lipids, but there are only small amounts of alkylglycerol lipids suggesting a link between alkyl-diacylglycerols and triacylglycerol formation<sup>119</sup>. But are these observations only symptoms or the actual cause of a defect in E-signaling, as *asg* and *csg* mutants reveal the same symptoms?

At this point, the findings presented in **Chapter 6.2** come into play. **SI Table 4** in **Chapter 6.2.5** shows triacylglycerol levels of starved *elbD* (*MXAN\_1528*) mutant cells. As expected, they are on a low level in both cases in vegetative cells and strongly accumulate after 24 h of nutrient downshift in the wild type. In contrast to this, the *elbD* mutant shows a rather selective loss in alkylglycerol formation with a similar increase in all other glycerolipid species, which suggests the formation of lipid bodies without the formation of alkylglycerols and no impact on the overall relative amount of iso-branched fatty acids (**SI**

**Table 3, Chapter 6.2.5).** Contrary to the LS1191/HB015 mutants, all molecular species from any biosynthetic pathways, including the IV-CoA dependent isoprenoid formation but except those derived from alkylglycerols, are available at wild type levels. Considering the phenotype of *elbD* (**SI Figure 1, Chapter 6.2.5**), the early developmental events like aggregation and mound formation are delayed and viable spores are not detectable, whereas the overall fruiting body formation is similar to the wild type. In a situation where *elbD* is genetically complemented with *elbD* under the control of a constitutive promoter, alkylglycerol levels as well as the developmental phenotype are restored with an improved, but still strongly disturbed, differentiation into viable spores. A mutant with the same constitutive expression of *elbD* in a wild type background (*elbD*<sup>+</sup>) yielded a similar phenotype with the expected higher levels of alkylglycerols (**SI Figure 1, Chapter 6.2.5**).

This line of evidence strongly suggests that the iso-branched ether lipids are an important component of the E-signal. They need to be formed chronologically in sufficient amounts in order to ensure timed aggregation as well as formation of viable spores. But why is i15:0 such a good remedy for mutants LS1191 and DK5624, even better than TG-1? In the light of the data from **Chapter 6.1**, it seems that one investigates two parameters at a time when i15:0 is used to complement a *bkd*, *bkd/mvaS* or *bkd/MXAN\_4265 (aibB)* mutant. In all cases, formation of iso-branched compounds is more (*bkd/mvaS*, *bkd/MXAN\_4265 (aibB)*) or less (*bkd*) severely hampered. At the same time IPP biosynthesis from IV-CoA is only reduced in a way that IV-CoA cannot be acquired from leucine (all mutants) or leucine and 3-HMG-CoA (*bkd/mvaS*, *bkd/MXAN\_4265 (aibB)* mutants). However, IVA and DMAA, intermediates in the mevalonate-dependent IVA biosynthesis, can both be effectively utilized for isoprenoid biosynthesis as shown for geosmin<sup>109</sup>. The same is easily imaginable for i15:0 as its final  $\beta$ -oxidation product is IVA, which would mean that i15:0 does not only substitute for iso-branched lipids but also for insufficient isoprenoid biosynthesis. The developmental phenotype of HB020 (**Figure 3, Chapter 6.1**) suggests that a restoration of the *bkd* phenotype is possible on a macroscopic level, solely by providing more 3-HMG-CoA for isoprenoid biosynthesis. Unfortunately, no microscopic images from 6-24 h of starvation induced fruiting body formation are available, so that a comparison of strain HB020 with the *elbD* mutant is not possible for this time frame and it has never been shown directly that iso-odd fatty acids are precursors for terpenoids in *M. xanthus* so that the final evidence for this hypothesis is missing. At least, extensive  $\beta$ -

oxidation of externally fed [ $^2\text{H}_7$ ]i15:0 is proven for *bkd* mutants of *Stigmatella aurantiaca* under vegetative conditions<sup>125</sup> so that this hypothesis is not far-fetched at all.

In conclusion, the presented data shows that a sufficient IPP supply for isoprenoid biosynthesis is important for fruiting body formation and the timely defined biosynthesis of iso-branched alkylglycerols in some, yet to be determined form, yields important signaling molecules that orchestrate the proper differentiation into viable, heat and sonication resistant spores. In order to unveil the true nature of the morphogenic iso-branched ether lipid molecule(s) the author suggests to check first if externally fed MG(O-15:0/0/0/0:0) is able to complement the phenotype of *elbD* and, a *bkd*, *liuC* double mutant, in a dose dependent manner. Utilization of this molecule ensures that no additional i15:0 fatty acid is present and the bioavailability should be improved compared to TG-1 due to the amphiphilic nature of this molecule. If this molecule proves to be active, feeding a chemically labeled analog of this molecule (may it be deuterated, radiolabeled or azido/alkyne labeled to allow click chemistry) during the course of development and cell differentiation along with appropriate analytics will auspiciously lead to the molecules which are so crucial for sporulation.

No matter how the actual E-signal molecule looks like: lipids are no molecules that can easily diffuse between cells through an aqueous environment and penetrate membranes of due to their poor water solubility and unfavorable partition coefficient<sup>126</sup>. Apart from the exact nature of the E-signal molecule(s), the way they are transferred from one cell to the other should be a subject for further research. An investigation of the proteome of outer membrane vesicles shed from vegetatively growing and starved *M. xanthus* cells led to the astonishing result that E1 subunit BCKAD proteins are transported within these vesicles<sup>127</sup> so that cells are probably able to deliver the enzyme activity necessary for E-signal formation or a lipophilic small molecule representing the E-signal. The same study also found a FadL homologue MXAN\_7040 (putatively responsible for fatty acid uptake) and at least one putative lipase (MXAN\_0220) so that it seems not unlikely that the complementation activity of TG-1 towards *bkd* mutants might be mediated by the i15:0 fatty acids after their hydrolytic release from the glycerol backbone. As a peculiar feature of motile *M. xanthus* cells, it was discovered that they are able to transfer lipids and proteins of their outer membrane upon direct contact on a solid surface as it was demonstrated for the motility proteins Tgl, CglB<sup>128</sup> as well as for fluorescent proteins directed to the outer membrane<sup>129</sup> and lipophilic dyes<sup>130</sup>. This kind of contact dependent

intercellular signaling is an easily conceivable way to transfer a lipophilic signaling molecule. Testing the concentration dependent ability of purified subcellular fractions of wild type cells for complementation activity on *bkd* mutants should demonstrate if there is a distinct spatial distribution of the E-signal.

### 3.3 The biosynthesis of vinyl ether lipids by the action of ElbD: a proposal for a new biosynthetic pathway.

Extensive characterization of *elb* gene mutants with regard to fruiting body formation, sporulation, fatty acid and lipid profile demonstrated the pivotal role of the multidomain enzyme ElbD in ether lipid formation (**Chapter 6.2**). In addition to this, *in-vitro* and *in-silico* experiments on ElbD suggested the activities of the respective domains. By summarizing all the presented data, the author proposes a biochemical route as a working model of how this enzyme achieves the stepwise formation of an ether bond (**Figure 3.1 a**). It has to be emphasized that this working model is very likely incomplete in terms of missing *in-vitro* data of the acyltransferase and reductase domains activities. Nevertheless, the stepwise ether bond formation may occur like this:

The fatty acyl-CoA ligase activates a free isopentadecanoic acid via adenylation and transfer onto a phosphopantethein moiety attached to the T domain as it was shown *in-vitro* (see **SI Figure 6, Chapter 6.2.5 a and b**). Then the activated fatty acid is reduced to yield an aldehyde intermediate and then transferred to the 2-isopentadecanoyl-*sn*-glycero-3-phosphoethanolamine (PE(0:0/i15:0)) to yield a hemiacetal intermediate to be dehydrated to a vinyl ether probably by the action of ElbE (**Figure 3.1 a, pathway A**) afterwards. However, observed aldehyde formation could also exclusively derive from hemiacetal decomposition, so that it is also conceivable that the activated fatty acid is first transferred on PE(0:0/i15:0) and the resulting ester bond is subsequently reduced in an unusual reaction to a hemiacetal intermediate, which is later dehydrated (**Figure 3.1 a, pathway B**). The proposed involvement of PE(0:0/i15:0) is consistent with our *in-silico* data of the acylglycerol acyltransferase domain and the observed accumulation of PE(0:0/i15:0) in the *elbD* mutant (see **SI Table 6, Chapter 6.2.5**). The final product of this proposed pathway, VEPE (PE(*O*-i15:0/i15:0), see **Figure 1.4**), accumulates during starvation induced fruiting body formation<sup>119</sup>. Further reactions by yet-to-be determined enzymes comprise hydrogenation of the  $\Delta^1$  double bond, hydrolysis of the 1-alkyl,2-acylglycerophosphoethanolamine head group (by a phospholipase C) and acylation of the free *sn*-3 hydroxyl group of the alkylacylglycerol (via a diacylglycerol *O*-acyltransferase)

with an activated isopentadecanoic acid to yield TG-1 or isoheptanoic acid to form its derivative TG(*O*-i15:0/i15:0/i17:0), which both accumulate in the aforementioned lipid bodies<sup>120</sup>.

To date, there are no experimentally confirmed examples for neither the reduction and dehydration of an ester bond nor the transfer of a fatty aldehyde. Acetal formation is well known from starch biosynthesis elicited by the starch synthase (EC 2.4.1.21), but this reaction requires activation of the glucose with ATP so that there is no need to stabilize a hemiacetal intermediate<sup>131</sup>.

Nevertheless, there is one important, well-described example of 1-(1*Z*-alkenyl),2-acylglycerophosphoethanolamines formation with inextricability of acetal formation in literature: metabolic pulse and pulse-chase labeling studies with [<sup>32</sup>P] orthophosphate on *Clostridium butyricum*, whose membranes are also made of substantial amounts of 1-(1*Z*-alkenyl),2-acylglycerophosphoethanolamines, showed that these bacteria form first diacylglycerophosphoethanolamines, then unusual glycerol acetals of glycerophosphoethanolamines, then 1-(1*Z*-alkenyl),2-acylglycerophosphoethanolamines, which can be finally converted into the complex glycerophosphoethanolamine acetals of 1-(1*Z*-alkenyl),2-acylglycerophosphoethanolamines (**Figure 3.1 b**<sup>132,135,136</sup>).

### Figure 3.1 | Formation of 1-(1*Z*-alkenyl),2-acylglycerophosphoethanolamines

**a:** Proposed ElbD mediated ether lipid biosynthesis in *M. xanthus* and other myxobacteria as deduced from experimental data presented in **Chapter 6.2**. For details see text. **b:** Order of [<sup>32</sup>P] orthophosphate incorporation in glycerophosphoethanolamine species of *Clostridium butyricum*<sup>132</sup> (**A**) and proposed biosynthesis of 1-(1*Z*-alkenyl),2-acylglycerophosphoethanolamines species for *C. novyi*<sup>133</sup> (**B**). Note the formation of diacylglycerol species before 1-(1*Z*-alkenyl),2-acylglycerophosphoethanolamines are formed. 1-alkyl,2-acylglycerophosphoethanolamines are absent in *Clostridia*. **c:** Ether bond formation as determined for humans and other mammals<sup>134</sup>. The ether bond is formed before the polar headgroup is introduced. Vinyl ether bond formation is the last step. Enzymes in pathway c: **A:** glycerone-phosphate O-acyltransferase (EC 2.3.1.42); **B:** alkylglycerone-phosphate synthase (EC 2.5.1.26); **C:** acylglycerone-phosphate reductase (EC 1.1.1.101); **D:**alkylglycerolphosphate 2-O-acyltransferase ((EC 2.3.1.-); **E:** phosphatidate phosphatase (EC 3.1.3.4); **F:** ethanolamine-phosphotransferase (EC 2.7.8.1); **F:** ethanolamine-phosphotransferase (EC 2.7.8.1); **G:** plasmalethanolamine desaturase (EC 1.14.99.19); Abbreviations: P: phosphate; CoA: coenzyme A; CDP-Etn: cytidin diphosphate ethanolamine; CMP: cytidin monophosphate; X: uncharacterized hydrogen donor; PE: phosphatidylethanolamine; Re: acyl-CoA(ACP)-like reductase; A: fatty acyl-CoA (ACP) synthetase; T: acyl carrier protein /thiolation domain; AT: acylglyceronephosphate acyltransferase. Dashed arrows indicate multiple reaction steps.

These results were later confirmed for *Clostridium novyi* NT<sup>137</sup> and *Clostridium tetani*<sup>133</sup> strains, whereas they do not form glycerol acetals, but also exhibit a high proportion of 1-(1Z-alkenyl),2-acylglycerophosphoethanolamines. Additionally, 1-enyl chains were barely detectable in precursor lipids like glycerophosphates, CDP-diacylglycerols and glycerophosphoserines, thus further strengthening the hypothesis of a glycerophosphoethanolamine being formed before the introduction of the vinyl ether bond. Glycerol acetals were not found in *M. xanthus* during the study presented in **Chapter 6.3**, but they might be present in vanishingly small traces. There are no clear homologues of *elbD* or its single domains present in sequenced *Clostridium* genomes, but both a fatty-acyl CoA reductase activity yielding aldehydes as well as the formation of plasmalogens by incorporating exogenously added fatty aldehydes were demonstrated for *C. butyricum*<sup>138-140</sup>. These observations contrast with the well-studied mammalian ether lipid biosynthetic pathway<sup>134</sup> (**Figure 3.1 c**). Here, alkyl ether bond formation occurs via a substitution of an esterified fatty acid with a fatty alcohol (**Figure 3.1 c**, step **B**). The dehydrogenation reaction to yield a vinyl ether bond takes place in the last step of 1-(1Z-alkenyl),2-acylglycerophosphoethanolamines formation (**Figure 3.1 c**, step **G**).

The intensive and unsuccessful efforts spent on obtaining fully active, heterologously expressed ElbD (see online methods, **Chapter 6.1**) *in-vitro* and *in-vivo* promise a complex and exciting biochemistry behind ether bond formation. Even *ElbD<sub>DW</sub>*, which is the ElbD homologue from *Stigmatella aurantiaca*, failed to be active when expressed in *M. xanthus* (**SI Figure 1 a and b**, **Chapter 6.2.5**) despite its high level of sequence identity (**SI Data Set 2**, **Chapter 6.2.5**). The direct overexpression of tagged ElbD in *M. xanthus* cells will be a potentially more promising method to achieve fully active ElbD than the use of other bacteria as heterologous host. Additionally, this will also conceivably offer means for the discovery of additional enzymes required for the underlying biochemistry. Only during starvation induced fruiting body formation, there is a strong increase in ether lipid formation in *elbD/elbD<sup>+</sup>* mutants, although the complementing gene is under control of a constitutive promoter (**SI Figure 1 b**, **Chapter 6.2.5**), which argues for other developmentally controlled genes being involved in ether lipid formation. The purification of homologously expressed ElbD under carefully controlled conditions potentially results in the co-purification of additional biosynthetic enzymes, which should be identifiable by means of peptide mass fingerprinting<sup>141</sup>. Such an approach was already successfully

utilized during the investigation of A-motility. It enabled researchers to unveil the interplay of several A-motility proteins<sup>64,66</sup>(see **Chapter 1.2.3**).

### **3.4 Known biological functions of alkyl ether lipids and their putative roles in *M. xanthus*.**

The data presented in **Chapter 6.2** and those from previous investigations on myxobacterial ether lipids<sup>119,124</sup> strongly suggest signaling functions elicited by an alkylglycerol containing lipid or some other molecule derived thereof. The observation that i15:0 is an even better agent to complement the E-Signal deficient *bkd*, *bkd/mvaS* or *bkd/MXAN\_4265 (aibB)* mutant is explainable as it acts as both a precursor of the isoprenoids and iso-branched ether lipids (see **Chapter 3.2**). But what do these molecules possibly look like and what could be their molecular target? Two signaling functions of ether lipids are known from higher organisms: The pro-inflammatory activity of the platelet-activating factor (PAF, 1-*O*-hexadecyl-2-acetyl-sn-glycero-3-phosphocholine) and the protein kinase C (PKC) activity modulating alkylacylglycerols.

PAF is produced by numerous cells of the human body that are associated with immune defense and hemostasis such as macrophages, monocytes, neutrophils, platelets, and endothelial cells. Its release mediates a number of pro-inflammatory effects like increase in vascular permeability, degranulation, release of cytokines and platelet activation<sup>142</sup>. Numerous other physiological and developmental processes including neuronal activity, spermatogenesis and embryo development also involve PAF. Its activity is transduced into target cells by its own G-protein coupled receptor<sup>143</sup> and the signal is further propagated by release of the second messengers inositol-1,4,5,-trisphosphate (IP<sub>3</sub>) that usually derive from the phospholipase C mediated hydrolysis of glycerophosphoinositol-4,5-trisphosphate (PIP<sub>2</sub>)<sup>144</sup>. The activation of several protein kinases typically involved in signal transduction (e.g. protein kinase C (PKC) and A (PKA) as well as mitogen activated protein kinase (MAPK)) were also found to be part of PAF signaling pathways<sup>142</sup>. Astonishingly, this provides a link to the activity of 1-alkyl,2-acylglycerols. As mentioned before, they affect the activity of protein kinases *in-vitro*. PKCs that are overactivated due to a mutation or the activity of the strongly agonistically acting phorbol esters are involved in tumorigenesis<sup>145</sup>. Contrary to this, alkylacylglycerols can inhibit the activity of PKCs as well as growth of certain tumorous cell lines *in-vitro*<sup>146,147</sup>, and when supplemented in human dietary, they were shown to increase the survival of cancer patients or reduce the extent of side effects by radiation treatment<sup>148,149</sup>. It should not go unmentioned that the activity of

alkylmonoacylglycerols depends on the isoforms of PKCs. For example PKC  $\beta$  is stimulated by ether linked diglycerides but PKC isoforms  $\delta$  and  $\epsilon$  show significant inhibition *in-vitro*<sup>150</sup>. PKCs belong to the serine-threonine kinase family proteins (EC 2.7.11.-). As mentioned in **Chapter 1.1.2**, there is a striking number of serine-threonine kinases encoded in the genome of *M. xanthus*, but they are essentially uncharacterized so that one can only speculate about their involvement in alkylglycerol mediated signaling in myxobacteria<sup>27</sup>.

Yet, a signaling role cannot solely explain the strikingly high amounts of alkyl diacylglycerol lipids found in lipid bodies during sporulation. They may simply be a special kind of temporary carbon storage similar to the triacylglycerols in adipocytes. At the same time, alkylglycerols are possibly covalently incorporated into the spore coat: Firstly, alkylglycerols in the form of i15:0-*O*-alkylglycerol bisTMS make up a high proportion of methanolized spore material as determined by GC-MS<sup>119</sup>. Secondly, during spore differentiation the spore coat thickens while the lipid bodies diminish<sup>120</sup>. However, further evidence for this hypothesis is missing as the exact composition of the myxobacteria spore coat is hardly established<sup>151,152</sup>.

### 3.5 Plasmalogens: putative functions in an unusual host

Fatty acid derived vinyl ether lipids show a highly remarkable distribution among the tree of life. They are highly abundant in strictly anaerobically living organisms (e.g. bacteria comprising genera *Clostridia*, *Megasphaera*, *Vellonella*, and protozoa comprising *Isotricha* and *Dasytricha*; they are virtually absent in aerobically and facultatively anaerobic bacteria, plants and fungi and again common among all vertebrates including mammals and invertebrates<sup>153,154</sup>. Thus, the usually strictly aerobically (with the exception of *Anaeromyxobacter*<sup>20</sup> species) living myxobacteria are a remarkable exception. Membranes inhering plasmalogens show a number of physicochemical differences compared with those exclusively made up of diacylglycerophospholipids. With respect to their thermal phase behavior, lipids exclusively containing alk-(1Z)-enyl residues attached to the *sn*-1 position of the glycerol backbone show a slightly smaller (4-6 °C) transition temperature from the ordered gel phase to the liquid crystalline phase and a strongly (~38 °C) reduced transition temperature from the liquid crystalline to the non-lamellar reversed hexagonal phase<sup>150,155,156</sup>. These changes cause an increased permeability for ions (as shown for K<sup>+</sup> ions<sup>157</sup>) and promote their ability to fuse with other membranes<sup>158</sup>. These

properties may explain their high abundance in conductive tissue (e.g. myelin sheath) or synaptosomal membranes in which vesicular fusion events occur with high frequency<sup>159</sup>. In addition to this, the high susceptibility of the vinyl-ether bond to oxidation by reactive oxygen species (ROS) seems to serve as part of a general protection mechanism of cells against those harmful oxidants. Cells defective in the peroxisomal ether lipid biosynthesis are more susceptible to ROS and regain wild type susceptibility when plasmalogen levels are replenished by addition of alkylglycerols that serve as precursors for plasmalogens biosynthesis<sup>160</sup>.

Both the change in membrane behavior and the antioxidative properties are beneficial for myxobacteria during sporulation and may explain their increased formation. Rod-shaped vegetative cells have to be reshaped to spherical spores thus increasing the overall curvature of the membranes. The outer membrane sloughs off in favor of the mounting spore coat by outer membrane transfer<sup>127,128</sup> whereat the lipid bodies bud at the inner membrane<sup>120,124</sup> at the same time so that there is a need of greater membrane flexibility. It is unknown if oxidative stress increases during sporulation, but an alleged role of myxobacterial plasmalogens in protection against ROS similar to those evident from mammalian cells does not seem devious. Here again, an in-depth analysis of the lipidome, lipid body formation and cell differentiation of mutant cells compared to that of wild type cells during the course of fruiting body formation and sporulation, particularly with respect to metabolic intermediates, can help identify additional roles of these peculiar lipids.

### **3.6 A new UPLC-MS based lipidomics analysis: a perspective for the investigation of lipid biosynthesis in myxobacteria as well as molecules that orchestrate development and differentiation**

There are only few reports in the literature on lipid composition in myxobacteria<sup>116,117,161,118</sup>, only one on biosynthesis of polar lipids<sup>116</sup> and none that displays the individual molecular composition of a myxobacterial lipidome with respect to all expected lipid classes. The method described in **Chapter 6.3** has a number of attractive, favorable features: a standard column chemistry, the use of a fairly simple solvent system and a common buffer system without any further additives plus a sample workup based on the well-known lipid extraction procedure first described by Bligh and Dyer<sup>162</sup>. The resulting data set is suitable for both statistical analysis and sophisticated data display as shown by MathLab plots in **Figures 11-12 (Chapter 6.3)**. The sensitivity and specificity of this method can be further extended by increasing the bed length of the column or the

use of a high resolution mass spectrometer. An increase in accuracy concerning the relative abundance of lipid molecular species is achieved by the additional use of appropriate internal standards, and absolute quantification of individual molecules is imaginable as long as the respective genuine standards are available. Though we could not establish an example, this method can be used to read out *in-vitro* assays for enzymes involved in lipid biosynthesis without the, still very common<sup>137,163-165</sup>, use of radioactively labeled substrates as many conceivable lipid substrates, intermediates or final products are detectable with respect to abundance and molecular composition. Nonetheless, a comparative lipidomics approach will become crucial for the exact assignment of genes potentially involved in complex lipid biosynthesis as a common pitfall in assigning genes to their specific functions in myxobacteria is the presence of paralogous genes and convergent biosynthetic routes. For example, two biosynthetic routes lead to the formation of precursors for branched-chain fatty acids as shown in **Figure 1.4** and there are five different genes encoding 1-acylglycerol-3-phosphate *O*-acyltransferase homologues (EC 2.3.1.51, PlsC1, MXAN\_3330; PlsC2, MXAN\_3969; PlsC3, MXAN\_5578; PlsC4, MXAN\_0955; PlsC5, MXAN\_0147) present in the genome<sup>116</sup> of *M. xanthus* so that gene inactivation experiments do not necessarily result in an unambiguous loss of a certain metabolite just as shown for ether lipids in **Chapter 6.2**. Statistical analysis of mutant vs. wild type lipidome may unveil the subtle changes that are caused by the inactivation of genes whose functions can be partially complemented by paralogous genes. A comparable, but exclusively qualitative, approach was successfully applied in the attempt to identify novel secondary metabolites from *M. xanthus*, as described in **Chapter 1.1.2**,<sup>39,166</sup> and statistical analysis was applied in **Chapter 6.2** to unambiguously show the involvement of ElbD in ether lipid formation. Based upon their homology<sup>29</sup>, candidate proteins that may be involved in lipid biosynthesis are, apart from the aforementioned 1-acylglycerol-3-phosphate *O*-acyltransferase homologues, the putative phosphatidate cytidyltransferase MXAN\_2556 (EC 2.7.7.41, CdsA) and phosphatidylserine decarboxylase MXAN\_3724 (EC 4.1.1.65, Psd), both probably involved in glycerophosphoethanolamine biosynthesis. Phosphatidylglycerolphosphate synthase MXAN\_4626 (EC 2.7.8.5, PgsA) and cardiolipin synthase homolog MXAN\_0537 (EC 2.7.8.-, Cls) are candidates for glycerophosphoglycerol and cardiolipin synthesis, respectively and CDP-diacylglycerol-inositol 3-phosphatidyltransferase MXAN\_0450 (EC 2.7.8.11), inositol phosphorylceramide synthase MXAN\_0451 (EC 2.7.1.-) and *myo*-inositol-1-phosphate

synthase MXAN\_0452 (EC 5.5.1.4 ) may all be responsible for the biosynthesis of the newly discovered ceramide phosphoinositols described in **Chapter 6.3**.

Analogously, it is now possible to determine changes in the lipid composition qualitatively and quantitatively during different stages of growth and development, e.g. at certain time points of starvation induced fruiting body formation so that the remodelling of the membranes can be precisely tracked.

## 4 Concluding remarks

### 4.1 The biochemistry of proteins as a future challenge

The introduction of this thesis and the references in particular demonstrate how the ever advancing molecular genetic methods in combination with phenotypic analysis allowed researchers to learn an impressive quantum about the way *M. xanthus* organizes its fascinating lifestyle by utilizing its genomic potential. Nevertheless, in most cases data on the true activity of the identified proteins are lacking. Consequently, many questions remain unanswered: What are the receptors for the A-signal amino acids or for the CsgA proteins, respectively (**Chapter 1.3.4** and **1.3.6**)? What are the substrates of the LonD-like protease that is inactivated in the *bsg* mutants (**Chapter 1.3.5**)? What is the oxidation product from monoacylglycerophosphoethanolamine after oxidation by SocA (**Chapter 1.3.6**)? Finally, an issue that concerns this thesis: what is the mode of action of ElbD (**Chapter 6.2**)? Those questions could be continued ad infinitum. The fundamental issue at hand is that it is by far more laborious, time and resource demanding to find specific substrates and/or interaction partners of particular proteins than to perform certain molecular genetic experiments. Nowadays, whole genomes can be sequenced and annotated with reasonable efforts<sup>167</sup> and a few researchers can easily produce and screen hundreds of mutants yielded by transposon mutagenesis<sup>84</sup> but will hardly be able to screen the same number of protein products for their activity. All the *in-silico* methods known to infer protein functions by sequence comparisons may be sufficient to guide experiments but fail if the moot protein belongs to a previously unknown class or unfolds a different function than expected<sup>168</sup>. Heterologous expression of genes with the intention to acquire soluble, active proteins to test their functions with the appropriate assay is still a subject of trial and error and rather resembles throwing the dice than rational science<sup>169</sup>. The only feasible and rational approach to perform such a task in a large scale is an increased use of automation systems in combination with thorough and rational test designs. Though hardly used in academic laboratory environments, all sorts of laboratory automation systems are already in use for high-throughput applications such as automated cloning<sup>170</sup>, protein expression and purification<sup>171,172</sup> as well as protein crystallization<sup>173,174</sup>. Additionally, countless methods to screen for enzyme activity are known<sup>175-178</sup> and there are examples for automated protein production strategies from DNA preparation to protein purification and analysis<sup>179,180</sup> indicating that they are no dreams of the future. It is rather a general

question of resource allocation, division of labor and organizational structures if these technical achievements speed up progress in the quest to decipher protein functions or remain barely used. Such data sets can be used to answer particular questions as well as to provide valid bases for activity predictions. Recently, it was shown that as long as sufficient data on the substrate specificity and the structural constitution of a certain enzyme class is available, mathematical models can be constructed which allow the prediction of the substrate specificity of an unknown protein sequence from the same enzyme class<sup>181</sup>. This approach still has to prove itself, however could mean a real breakthrough in enzymology. A switch from individual, manually performed biochemical efforts to elucidate protein functions to thoroughly planned, automated large-scale endeavors will provide more facile and comprehensive answers on the mechanisms that protein evolve to shape the processes in myxobacterial cells.

## **4.2 Publications derived from additional projects: gas chromatography coupled to mass spectrometry as a versatile tool to fathom and monitor biological processes**

Throughout the whole work, GC-MS was one of the most important tools to monitor changes in the composition of the fatty acid pattern of *M. xanthus* with the vinyl ether derived dimethylacetals and the alkylglycerol derived of i15:0-*O*-alkylglycerol bisTMS being the most important target components to monitor changes in the ether lipid production in the *elb* mutants (see **Chapter 6.2**). However, it should not go unmentioned that my expertise in GC-MS operation and method development was also required for numerous additional projects for which I supported colleagues and cooperation partner in their effort to elucidate different biological and biochemical questions. For a variety of reasons, some of these projects did not result in publications but others did with my humble self being co-author. Here are short summaries of the central subjects of those publications including short descriptions of my contributions. Details on these investigations are available in the original publications.

In “Myxotyrosides A and B, Unusual Rhamnosides from *Myxococcus* sp.”<sup>182</sup>, Ohlendorf *et al.* describe a novel group of natural products from *Myxococcus* sp. strain 131 named the myxotyrosides A and B. These molecules contain a tyrosine-related core structure, glycosylated with rhamnose at the phenolic hydroxy group and additionally acylated with fatty acids that are unsaturated at the  $\Delta^2$  position. My analysis of the fatty acid methyl ester pattern of *Myxococcus* sp. strain 131 provided the information that this strain does not have

these kinds of fatty acids as constitutive components of its cell membranes. This finding indicates that the  $\Delta^2$  unsaturated fatty acid moieties in the myxotyrosides are not acquired from primary metabolism but probably formed by the myxotyroside biosynthetic enzymes as discussed in the paper.

In an extensive metabolic engineering project, Brat *et al.* strived after the improvement of isobutanol production in *Saccharomyces cerevisiae* strains by relocating the valine biosynthetic genes from the mitochondrial matrix to the cytosol and overexpressing several other genes which protein products are involved in the catabolism of valine<sup>183</sup>. My effort was to establish and routinely carry out a GC-MS based method to analyze isobutanol formation from the headspace of cell culture supernatants including absolute quantification. Hence, the extent of isobutanol formation by fermenting *Saccharomyces* strains was traceable.

In the publication “Determination of the Absolute Configuration of Peptide Natural Products by Using Stable Isotope Labeling and Mass Spectrometry” we demonstrated that structures of peptides synthesized by NRPS can be fully elucidated by combining metabolic feeding experiments with HPLC-MS<sup>n</sup> analysis, thus circumventing compound isolation and NMR analysis<sup>184</sup>. In order to determine the absolute configuration of the  $\alpha$ -carbons within the peptide backbones, mutants defective in their amino acid transaminase activity were constructed, fed with fully deuterated amino acids and the relevant natural products were analyzed for the loss of label at the  $\alpha$ -carbons. A loss of deuterium label indicates D-, a preservation of the label L-configuration. As GC-MS is an excellent tool to analyze amino acids<sup>185</sup>, I established a method to determine the extent of the loss of deuterium label from the  $\alpha$ -carbons of fully labeled deuterated amino acids in cell free media supernatant at various time points. As a result, we were able to assess the decline of transaminase activity in transaminase mutants.

For the publication “Reciprocal Cross Talk between Fatty Acid and Antibiotic Biosynthesis in a Nematode Symbiont” GC-MS based determination of the fatty acid methyl ester pattern derived from methanolized cells was needed again<sup>186</sup>. In this work, we provided evidence that the BCKAD complex from *Xenorhabdus nematophila* HGB081 is involved in both the provision of starter units for branched-chain fatty acids as well as isobutyryl-ACP starting units for the biosynthesis of the natural product pristinamycin II<sub>a</sub>. GC-MS analysis confirmed that *E. coli* cells produce branched-chain fatty acids when

expressing genes encoding for the BCKAD complex from *Photorhabdus luminescens* TT01. In *Xenorhabdus nematophila* HGB081 the homologue of the gene encoding the E2 subunit of the BCKAD complex is part of the pristinamycin II<sub>a</sub> PKS/NRPS biosynthetic gene cluster. When disrupted, mutants lack pristinamycin II<sub>a</sub> production as well as formation of iso-branched fatty acids as determined by GC-MS.

## 6.1.1 Abstract

It was recently shown that *Myxococcus xanthus* harbors an alternative and reversible biosynthetic pathway to isovaleryl coenzyme A (CoA) branching from 3-hydroxy-3-methylglutaryl-CoA. Analyses of various mutants in these pathways for fatty acid profiles and fruiting body formation revealed for the first time the importance of isoprenoids for myxobacterial development.

## 6.1.2 Main text

Myxobacteria are unique among the prokaryotes as (i) they can form highly complex fruiting bodies under starvation conditions, even up to microscopic tree-like structures (28); (ii) they can move on solid surfaces using different motility mechanisms (16); (iii) they produce some of the most cytotoxic secondary metabolites, with epothilone already in clinical use against cancer (2, 3); and (iv) they harbor the largest prokaryotic genomes found so far (15, 27). The large genome might be directly related to their complex lifestyle and the diverse secondary (3) and primary (9) metabolisms. Already in 2002 we found that myxobacteria are able to produce isovaleryl coenzyme A (IV-CoA) and compounds derived thereof via a new pathway that branches from 3-hydroxy-3-methylglutaryl-CoA (HMG-CoA), which is the central intermediate of the well-known

mevalonate-dependent isoprenoid biosynthesis (**Fig. 1**) (22, 23). Usually IV-CoA is derived from leucine degradation via the branched-chain keto acid dehydrogenase (BKD) complex (24), which is also the preferred pathway to IV-CoA in the myxobacteria *Myxococcus xanthus* and *Stigmatella aurantiaca* (**Fig. 2A**). However, in *bkd* mutants, where no or only residual leucine degradation is possible (30), the alternative pathway is induced (**Fig. 2B**), presumably to ensure the production of iso-fatty acids (iso-FAs) (5). A possible reason for this alternative pathway is the importance of IV-CoA-derived compounds in the complex myxobacterial life cycle, which is the starvation-induced formation of fruiting bodies in which the cells differentiate into myxospores. We showed that this pathway is induced during fruiting body formation in *M. xanthus* when leucine is limited. Under these conditions, this pathway might be more important for protein synthesis than for lipid remodeling, as lipids are present in excess during development due to the surface reduction from vegetative rods to round myxospores as described previously (29). Examples of IV-CoA-derived compounds are the unusual iso-branched ether lipids, which are almost exclusively produced in the developing myxospores. They might serve as structural lipids and signalling compounds during fruiting body formation (26).

**FIG. 1.** Biosynthesis of IV-CoA and compounds derived thereof and biosynthesis of isoprenoids in *M. xanthus*. Broken arrows indicate multistep reactions; supplementation (double-lined arrows) with MVL and IVA can be used to complement selected mutants.

**FIG. 2.** Short representations of proposed metabolic fluxes through the IV-CoA/isoprenoid network. Broken arrows indicate no metabolic flux. (A) DK1622 (wild type); (B) DK5643 ( $\Delta bkd$ ); (C) DK5624 ( $\Delta bkd mvaS::kan$ ); (D) HB002 ( $\Delta bkd liuC::kan$ ); (E) HB002 with 1 mM IVA; (F) HB002 with 1 mM MVL. Ac-CoA, acetyl-CoA; MVA, mevalonic acid.

**FIG. 3** (previous page). Fruiting body formation on TPM agar in selected mutants at 24, 48, and 72 h after starvation. Numbers refer to the relative amounts (in percentages) of the most abundant iso-FA, iso-15:0, which is indicative of iso-FAs in general. Strains were DK1622 (wild type), HB002 ( $\Delta bkd\ liuC::kan$ ), HB015 ( $\Delta bkd\ MXAN\_4265::kan$ ), DK5624 ( $\Delta bkd\ mvaS::kan$ ), HB019 ( $\Delta bkd\ mvaS::kan\ mvaS^+$ ), and HB020 ( $\Delta bkd\ MXAN\_4265::kan\ mvaS^+$ ). DK5624 was grown with 0.3 mM MVL prior to starvation, and the cells were washed and plated on TPM with or without 1 mM of MVL.

In *M. xanthus*, we could recently identify candidate genes involved in the alternative pathway from HMG-CoA to IV-CoA. We also described the genes required for the degradation pathway of leucine and subsequently also those involved in the transformation of IV-CoA to HMG-CoA (4). In myxobacteria leucine is an important precursor for isoprenoid biosynthesis, as was already shown elsewhere for the biosynthesis of steroids (7) and prenylated secondary metabolites like aurachin (22) or leupyrrins (6), as well as volatiles like geosmin or germacradienol in *M. xanthus* and *S. aurantiaca* (11, 13). The interconnection of iso-FAs and isoprenoid biosynthesis made it difficult to assign functions to these compound classes during fruiting body formation in *M. xanthus* because it cannot be excluded that reduced leucine degradation also impairs isoprenoid biosynthesis. A mutant strain of *M. xanthus* that was blocked in the degradation of leucine and the alternative pathway had a deletion in the *bkd* locus as well as a plasmid insertion in the *mvaS* gene encoding the HMG-CoA synthase (strain DK5624). This double mutation severely affected isoprenoid biosynthesis (5), and cultures of DK5624 must be supplemented with mevalonolactone (MVL; the cyclized form of mevalonic acid) in order to enable growth (**Fig. 2C**). Since we have identified the genes involved in IV-CoA biosynthesis and the mevalonate pathway (4), we can now start to identify differences between strains that show deficiencies in iso-FAs and strains that show deficiencies in isoprenoids via simple analysis of the FA profile and analysis of the myxobacterial development of selected mutants.

All mutants used in this study (HB002 [ $\Delta bkd\ liuC::kan$ ], HB015 [ $\Delta bkd\ MXAN\_4265::kan$ ], DK5624 [ $\Delta bkd\ mvaS::kan$ ], HB019 [ $\Delta bkd\ mvaS::kan\ mvaS^+$ ], and HB020 [ $\Delta bkd\ MXAN\_4265::kan\ mvaS^+$ ]) have been published previously (4), and FA analysis as well as myxobacterial fruiting body formation has also been described previously (26).

*M. xanthus* HB002 ( $\Delta bkd\ liuC$ ) shows only residual amounts of iso-FAs, as both leucine degradation and the alternative pathway to IV-CoA are blocked (**Fig. 2D**) and its capability to form fruiting bodies is strongly reduced (**Fig. 3**). The residual amount of iso-FAs results

from a second BKD activity in *M. xanthus* that has been identified by residual leucine incorporation as well as by residual enzymatic activity in *bkd* mutants (23, 30). This second BKD activity might be a side activity of the pyruvate dehydrogenase or a related chemical oxidative decarboxylation, as no second *bkd* locus could be identified in the genome (unpublished results). Moreover, growth of HB002 is not MVL dependent because the block in the alternative pathway does not affect isoprenoid biosynthesis, as *liuC* encodes a dehydratase/hydratase that is involved in the conversion of HMG-CoA to 3-methylglutaconyl-CoA and vice versa (4). As expected, the FA profile (4) as well as the developmental phenotype (data not shown) can be complemented (**Fig. 2E**) by the addition of isovaleric acid (IVA), the free acid of IV-CoA, indicating the importance of iso-branched compounds for development in *M. xanthus*. Unexpectedly, addition of MVL (**Fig. 2F**) also partially restored fruiting body formation without restoring the FA profile (**Fig. 3**). Similarly, *M. xanthus* HB015 ( $\Delta bkd$  MXAN\_4265::kan) can produce only traces of iso-FAs, as both pathways to IV-CoA are blocked. MXAN\_4265 encodes a protein with similarity to a glutaconyl-CoA transferase subunit, but from our previous results, we postulated it to be involved in the alternative pathway to IV-CoA (**Fig. 1**) (4). The respective mutant shows a severely impaired developmental phenotype, which can be complemented not only by the addition of IVA (not shown) but also by the addition of MVL (**Fig. 3**). Again, no change in the FA profile was observed after the addition of MVL. However, a plasmid insertion into MXAN\_4265 has a polar effect on *mvaS*, which is the last gene in this five-gene operon and which is crucial for HMG-CoA formation from acetoacetyl-CoA and acetyl-CoA. Therefore, we assume that both pathways to HMG-CoA are blocked in HB015: no HMG-CoA can be made from acetyl-CoA and hardly any can be made via leucine degradation. In order to prove this hypothesis, we complemented HB015 with an additional copy of *mvaS* under the constitutive T7A1 promoter as described previously, using the plasmid pCK4267exp (4). The resulting strain, HB020 ( $\Delta bkd$ , MXAN\_4265::kan *mvaS*<sup>+</sup>), showed a restored developmental phenotype but still produced only trace amounts of iso-FAs.

The data from HB002, HB015, and HB020 indicate an important function of the mevalonate-dependent isoprenoid pathway for fruiting body formation in *M. xanthus*. Therefore, MVL addition can at least partially complement the developmental phenotype of DK5624, which cannot form fruiting bodies without MVL (**Fig. 3**). However, genetic

complementation with *mvaS* in HB019 resulted in the expected complementation of the fruiting body formation and the FA profile (**Fig. 3**, bottom row).

Leucine is one of the most abundant proteinogenic amino acids. It is also an essential amino acid for *M. xanthus* (8), which has a predatory life-style (1), as it lives on other bacteria and fungi that contain a lot of leucine. Moreover, leucine is very efficiently incorporated into isoprenoids like geosmin and aurachin (10, 22). Thus, one can conclude that in fact leucine degradation is the major pathway for HMG-CoA biosynthesis instead of the usual formation via acetoacetyl-CoA and acetyl-CoA by the HMG-CoA synthase MvaS as indicated in **Fig. 2A**. No difference in growth was observed between culture with and culture without MVL for HB002 ( $\Delta bkd$  *liuC::kan*) and HB015 ( $\Delta bkd$  *MXAN\_4265::kan*) in rich medium (data not shown), probably due to the complete MvaS activity (in HB002) or residual BKD activity (in HB002 and HB015), resulting in all precursors for the mevalonate-dependent isoprenoid biosynthesis still being present in excess under these conditions. However, under starvation conditions a small reduction in HMG-CoA biosynthesis caused by completely blocked leucine degradation (as in HB002 due to the mutation in *liuC* [**Fig. 2D**]) or reduced leucine degradation and a mutation in *mvaS* (as in HB015) might each result in a reduced isoprenoid level, which can be complemented at least partially by the addition of MVL. This would also explain the difference in the developmental phenotypes of HB002 and HB015, with the phenotype being more severe in HB002 (**Fig. 3**). The fact that complementation with IVA is in all cases more efficient than that with MVL can be explained by the role of the already-mentioned isolipids. They can be produced only after IVA addition, which also complements the (developmental) phenotype of some of these mutants (26).

As isoprenoids represent probably the most diverse class of natural products (14), it is very hard to predict which particular isoprenoids might be responsible for the observed effects. Several isoprenoids (7, 11–13), prenylated secondary metabolites (6, 22), and carotenoids (18–21) are known from myxobacteria in general, and a major volatile compound from *M. xanthus* is the terpenoid geosmin (13). In order to test whether geosmin might be required for fruiting body formation, we constructed a plasmid insertion mutant in *MXAN\_6247*, which is involved in the cyclization of farnesyl diphosphate to geosmin, following published procedures (4, 5). The resulting strain, HB022, showed the expected loss in geosmin production but no developmental phenotype (data not shown).

Additionally, it cannot be excluded that prenylated proteins, sugars, or quinones from the respiratory chain are important for fruiting body formation. Moreover, stigmolone has been described as a pheromone involved in fruiting body formation in *S. aurantiaca* (25). Although its biosynthesis has not been elucidated yet, stigmolone could be an isoprenoid as well, which is deducible from the two iso-branched residues within its chemical structure (17). Nevertheless, the importance of isoprenoids for *M. xanthus* is evident from the data presented, and clearly more work is needed to identify the compound(s) involved.

## 6.2.1 Abstract

Fatty acid-derived ether lipids are present not only in most vertebrates but also in some bacteria. Here we describe what is to our knowledge the first gene cluster involved in the biosynthesis of such lipids in myxobacteria that encodes the multifunctional enzyme ElbD, which shows similarity to polyketide synthases. Initial characterization of *elbD* mutants in *Myxococcus xanthus* and *Stigmatella aurantiaca* showed the importance of these ether lipids for fruiting body formation and sporulation.

## 6.2.2 Main text

Vinyl ether lipids are frequently found in extremophile prokaryotes<sup>1</sup>, but to date, no genes related to their biosynthesis have been described. However, for *Megasphaera elsdenii*, *Veillonella parvula* and *Clostridium butyricum*, several studies showed that plasmalogen biosynthesis is not performed via dihydroxyacetone but with glycerol, and in *C. butyricum*, diacylglycerols were identified as precursors of plasmalogens<sup>2,3</sup>. We investigated ether lipid formation in the myxobacteria *M. xanthus* and *S. aurantiaca*<sup>4</sup>. These bacteria belong to the order myxococcales, which comprises Gram-negative, soil-dwelling, almost ubiquitous deltaproteobacteria that show social twitching motility and cooperative, wolf pack-like predatory feeding. Upon adverse environmental conditions, a temporally defined developmental program takes place, including aggregation, cell differentiation, fruiting body formation and sporulation<sup>5</sup>. We identified a number of unusual iso-branched vinyl- and alkyl ether lipids in *M. xanthus*, including plasmenylphosphatidylethanolamine (**Fig. 1a**; VEPE (PE(P-i15:0/i15:0), **1**; notation is as described by LIPID MAPS,

[http://www.lipidmaps.org/data/classification/LM\\_classification\\_exp.php](http://www.lipidmaps.org/data/classification/LM_classification_exp.php)) and plasmalanylphosphatidylethanolamine (AEPE (PE(*O*-i15:0/i15:0), **2**), 1-*O*-alkyl-*sn*-glycerol, 1-*O*-alkyl-2-acyl-*sn*-glycerol and 1-*O*-alkyl-2,3-diacyl-*sn*-glycerol, whereas the latter mentioned neutral ether lipids strongly accumulate in lipid bodies during the process of starvation-induced fruiting body formation<sup>4,6</sup>. In addition to that, a diacylmonoalkyl ether lipid named TG-1 (TG(*O*-i15:0/i15:0/i15:0) (**3**)) was recently found to act as a signaling molecule involved in the developmental program of *M. xanthus*<sup>7</sup>. Thus, we sought to further investigate the biosynthesis of these important molecules in myxobacteria.

As a starting point, we searched the genome of *M. xanthus* for possible gene candidates. The gene product of *MXAN\_1676* has 92% sequence coverage and about 42% identity to the human alkylglycerone-phosphate synthase (E.C. 2.5.1.26), which catalyzes the second step in peroxisomal ether lipid formation. However, gene disruption caused only a small reduction in ether lipid formation, indicating the existence of an alternative pathway (**Supplementary Results, Supplementary Fig. 1**). Therefore, we searched the genome for acyltransferases related to glycerolipid biosynthesis that have been previously disregarded<sup>8</sup>, resulting in the discovery of *MXAN\_1528*, which encodes a multifunctional protein with a domain annotated as acylglycerolphosphate acyltransferase of glycerophospholipid biosynthesis (AT). The gene is embedded in a five-gene operon (*MXAN\_1531–1527*), and its protein product additionally features a fatty acyl CoA-like reductase (Re), an acyl-carrier protein/thiolation domain (T) and an acyl-CoA synthetase domain (A) (**Fig. 1a**).

Insertion mutagenesis of *MXAN\_1528* yielded a phenotype with delayed aggregation between 6 h and 24 h after starvation-induced fruiting body formation, a strongly reduced content of vinyl and alkyl ethers under both vegetative and starvation conditions and no detectable viable spores and fewer fruiting bodies compared to the wild type (**Fig. 1b** and **Supplementary Fig. 1, Supplementary Data Set 1** and **Supplementary Table 2**). Accordingly, the *MXAN\_1531–1527* operon was renamed as *elbA–elbE* (where *elb* stands for ether lipid biosynthesis). Complementation of the *elbD* mutant restored both ether lipid formation and the developmental phenotypes, whereas overexpression in the wild-type background resulted in an acceleration of aggregation as well as a significant ( $P = 0.0011$ ) increase in monoalkylglycerol formation; in both cases, the strain's ability to form viable spores is strongly reduced (**Supplementary Fig. 1** and **Supplementary Table 2**). The changes in phenotype suggest a putative signaling function of a yet-to-be-determined ether

lipid molecule. Signaling functions of ether lipids have been shown in humans for the platelet-activating factor or monoacylmonoalkylglycerols inhibiting phosphokinase C (ref. 9), and, indeed, the development-specific alkyldiacylglycerol TG-1 can rescue the developmental phenotype of an *esg* mutant, which is impaired in the formation of a yet-to-be-determined intercellular signal<sup>7</sup>.

Gene disruption experiments in *elbA*, *elbB* and *elbE* (**Supplementary Fig. 1** and **Supplementary Table 2**) suggested that *elbA* is probably not involved in ether lipid formation as its disruption did not result in a specific phenotype. Disruption of *elbB* led to a similar but less pronounced phenotype than *elbD* in terms of ether lipid formation, which was partially restored by expression of *elbD*, suggesting that *elbD* is probably translationally coupled with *elbB* so that the observed effect was most likely due to a polar effect of *elbB* disruption. Finally, *elbE* seems to have a role in ether lipid formation as its inactivation caused a decrease in ether lipid formation that cannot be complemented by an extra copy of *elbD*. Concerning the developmental phenotype of the complementation mutants, it seemed that the constitutive expression of *elbD* disturbed the formation of viable spores. We did not deem this observation surprising as the amount of ether lipids is normally dependent on the stage of fruiting body formation<sup>4</sup>. Similarly, it has been shown that PE(16:1 $\omega$ 5c/16:1 $\omega$ 5c), a chemotaxis signal in *M. xanthus*, is only active at a specific concentration<sup>10</sup> and that the ability to complement an *esg* mutant by ether lipids follows a concentration-dependent saturation kinetics so that a high concentration is not necessarily beneficial for sporulation<sup>7</sup>.

**Figure 1 | Phenotypic investigation of the *elbD* mutant.** (a) Structures of the myxobacterial ether lipids VEPE(1), AEPE(2), the major diacylmonoalkyl ether lipid TG-1 (3); the constitution of the proposed ether lipid biosynthesis gene cluster in *M. xanthus*; and the predicted domain structure within ElbD (Supplementary Data Set 2). (b) Microscopic plan view on developing *M. xanthus* cells (scale bars, 500  $\mu$ m) with mean ( $n = 3$ )  $\pm$  s.d. of relative amounts of i15:0-DMA (top of each image) and of i15:0-OAG (bottom of each image), measured as the percentage of total fatty acid methyl esters. The results of the sporulation assay (italicized numbers in the ‘24 h’ column) are shown as mean ( $n = 3$ )  $\pm$  s.d. number of colony-forming units of percent wild type at 72 h and 120 h (values separated by slash), after starvation-induced fruiting body formation. \* $P < 0.05$ ; \*\* $P < 0.01$ ; \*\*\* $P < 0.001$  relative to wild type. NA: data not available. Details are in Supplementary Figure 1, Supplementary Table 2 and Supplementary Data Set 1.

As the notorious background level of vinyl- and alkyl ether lipids was a challenge for data evaluation and interpretation, we investigated *elbA*, *elbB* and *elbD* insertion mutants in *S. aurantiaca* DW4/3-1. The genes are arranged in the same way as in *M. xanthus*, and their protein products exhibit a very high homology (up to 90%). Additionally, *S. aurantiaca* does not have a *MXAN\_1676* homolog (**Supplementary Fig. 2** and **Supplementary Data Set 2**). As with *M. xanthus*, inactivation of *elbA* in *S. aurantiaca* did not result in a phenotype, but inactivation of *elbB* strongly decreased ether lipid content, and *elbD* brought ether lipid formation below the detection limit, strengthening the hypothesis that ElbD is involved in ether lipid synthesis. Starvation-induced aggregation behavior proved to be different in the *elbA*, *elbB* and *elbD* mutants compared to the wild type (**Supplementary Fig. 1** and **Supplementary Table 2**). Notably, *elbD* from *S. aurantiaca* was not able to complement the *M. xanthus elbD* mutant despite their high homology. All of the sequenced myxobacterial strains feature close homologs of at least *elbB–E* (**Supplementary Fig. 2**) and some homologs of *MXAN\_1676* (**Supplementary Data Set 2**), and all of the strains analyzed by gas chromatography (GC)/MS<sup>11</sup> contained ether lipids (**Supplementary Fig. 3**).

TLC analysis of total lipid extracts showed no obvious changes in phospholipid composition in an *elbD* mutant under vegetative conditions and 24 h after starvation induction, which is the time point with the highest abundance of ether lipids in the wild type<sup>4</sup>, but it did show a loss of one lipid species in the neutral lipid fraction (**Supplementary Fig. 4**). Additionally, GC/MS analysis of the methanolized fractions revealed that residual amounts of alkyl ether lipids were only detectable in the lysophospholipid fraction of the *elbD* mutant (**Fig. 2a** and **Supplementary Table 3**). This finding matches well with the eukaryotic peroxisomal ether lipid biosynthetic pathway, where 1-*O*-alkyl-*sn*-glycero-3-phosphates, not 1-*O*-alkenyl-*sn*-glycero-3-phosphates, are the first intermediates<sup>12</sup>. The lost neutral lipid species mentioned before turned out to be the 1-alkyl-2,3-diacyl-*sn*-glycerol that usually accumulates in lipid bodies under starvation conditions, whereas overall triglyceride biosynthesis was less affected (**Fig. 2b** and **Supplementary Tables 4, 5** and **11**)<sup>6</sup>. At the same time, lysophosphatidylethanolamines strongly accumulated in the lipid extract of starved *elbD* mutant cells (**Supplementary Tables 6** and **11**). High-performance LC (HPLC)/MS runs of freshly prepared lysophosphatidylethanolamine extracts from *elbD* mutants suggested that the fatty acyl

residue is bound to the *sn*-2 hydroxyl group of the glycerol backbone (**Supplementary Fig. 5**).

**Figure 2 | Differential analysis of lipid fractions and biochemical characterization of ElbD.** (a) Relative amounts of i15:0-OAG (dark gray) and i15:0-DMA (light gray), measured in percentage ( $n = 1$ ) of lipid fractions, as determined by fatty acid methyl ester (FAME) GC/MS analysis. NL, neutral lipids; PE, glycerophosphoethanolamine; PG, glycerophosphoglycerol; LysoPI, lysophospholipid. (b) High-temperature GC/MS analysis of neutral lipid fractions ( $n = 1$ ). Bars indicate amounts of lipids relative to the internal standard palmitylpalmitate (1,000 arbitrary units). (c) Enzymatic labeling of ElbD with fluorescent BODIPY-FL-CoA with (+) and without (-) Sfp. Average normalized fluorescence intensity is  $5.3 \times$  above control ( $n = 2$ ;  $R = 2.2$ – $8.4$ ). (d) F488-DBCO labeling of az15:0 loaded onto phosphopantetheinylated ACP domain of ElbD $\Delta$ re with (+) and without (-) az15:0 in the assay. Average normalized fluorescence intensity is  $4.7 \times$  above control ( $n = 2$ ;  $R = 2.8$ – $6.6$ ). C, Coomassie blue stain; FL, fluorescence; OL, overlay. Numbers indicate apparent molecular weight in kDa. Additional protein bands proved to be C-terminally truncated translation products (full gel pictures are in **Supplementary Figs. 6 and 7**, and MS analysis of the protein bands is in **Supplementary Tables 12–16**).

For initial biochemical characterization, ElbD was labeled *in vitro* with the fluorescent CoA analog BODIPY-FL-CoA by the phosphopantetheinyltransferase Sfp<sup>13</sup>, confirming a functional ACP domain (**Fig. 2c**). Similarly, auto-acylation of phosphopantetheinylated ElbD $\Delta$ re (ElbD without the reduction domain) was observed after treatment with ATP and a free azido fatty acid following the addition of a clickable fluorescent dye (**Fig. 2d**), demonstrating the protein's ability to activate long chain fatty acids, as further supported by *in silico* docking (**Supplementary Figs. 8 and 9**) and bioinformatic analysis<sup>14</sup> (**Supplementary Tables 7 and 8**). Unfortunately, attempts to functionally express *MXAN\_1531–1527* in *E. coli* did not result in ether lipid formation, as assessed by GC/MS.

For isolated ElbD, no acyltransferase domain protein activity was observable, preventing the exact evaluation of the activity elicited by the acyl transferase and reductase domain (Online Methods and **Supplementary Notes 1 and 2**). A phylogeny-based approach suggested that the acyl acceptor (**Supplementary Note 3, Supplementary Data Set 3 and Supplementary Fig. 10**) could be 2-lysophosphatidylethanolamine. This was further supported by its accumulation in *elbD* mutants (**Supplementary Tables 6 and 11**) as well as by *in silico* docking experiments with the predicted acyl acceptor substrates into the ElbD AT domain modeled upon the crystal structure of the glycerolphosphate acyltransferase from *Curcubita moscata* (**Supplementary Figs. 8b and 11**).

The reductase domain of ElbD is annotated as an acyl-CoA reductase (**Supplementary Data Set 2**). Such enzymes usually reduce CoA-bound fatty acids to fatty aldehydes or alcohols as part of wax ester biosynthesis<sup>15</sup>. However, we found neither fatty alcohols nor wax esters in the lipid extracts of *M. xanthus*. Therefore, we analyzed *M. xanthus* and *S. aurantiaca* cells for aldehyde formation as described<sup>16</sup>. Only i15:0 aldehyde could be identified in wild-type strains, and it was abolished in *elbD* mutants (**Supplementary Fig. 12**). We conclude from these findings that i15:0 aldehyde is the most likely product of the acyl-CoA reductase domain and is probably also involved in the formation of the vinyl ether bond.

Taking all of the results together, we have provided evidence that ElbD is involved in ether lipid biosynthesis, but more work will be needed to determine its biochemical mechanism. Although the exact functions of ElbABC remain unclear, it seems that they are dispensable for ether lipid formation or that their function can be complemented by other homologs encoded in the genome. Clues for a possible mechanism also come from Clostridia, which contain exclusively vinyl and no alkyl ether lipids. Here, metabolic labeling studies showed that, contrary to mammalian ether lipid biosynthesis<sup>12</sup>, diacylglycerophosphoethanolamines are formed before the vinyl moiety is introduced<sup>3</sup>, so our finding that only alkenyl- and not alkylacylglycerophosphoethanolamines are detectable in *M. xanthus* under both vegetative and developmental conditions (**Fig. 2a**) points to a possible ‘reductive’ ether lipid formation pathway. Additionally, the phosphatidylglycerol acetal of plasmenylethanolamine species, which require a hemiacetal intermediate in their biosynthesis, were described for *C. botulinum*<sup>17</sup>. *elbD* homologs can be found in many other bacterial genera, though the reductase domain is absent in most cases (**Supplementary Fig. 13**). Recently the multidomain enzyme DWA1, which is

involved in drought resistance and cuticular wax formation in *Oryza sativa* japonica rice, was described<sup>18</sup>; it has a domain structure similar to that of ElbD and has many homologs in other green vascular plants and bacteria but with an additional allene oxide synthase-like domain at the N terminus. The authors were able to prove A-domain activity but did not further investigate the activities of the other domains.

In summary, we have identified genes in myxobacteria that are involved in the formation of fatty acid derived ether lipids and provide a starting point for the evaluation of the sought-after ether lipid biosynthetic pathway in bacteria and their functions as well as the biotechnological production of ether lipids in bacteria. The latter aspect is of major ecological and technical importance because ether lipids for industrial, cosmetic and medicinal purposes are mainly obtained from shark liver oils<sup>19</sup>, which are highly complex mixtures that strongly hamper the extraction of pure, defined lipids<sup>20</sup> and, further, threaten an increasing number of endangered species whose overall population is assumed to be decreasing steadily<sup>21</sup>. As ether lipids are part of the regulation cascade for myxobacterial fruiting body formation, we expect that future work concerning the regulation of their biosynthesis as well as the identification of their molecular target (or targets) will unveil the molecular basis of this fascinating process.

### 6.2.3 Online methods

**Bacterial strains, culture condition, imaging and chemicals.** *M. xanthus* DK1622 and *S. aurantiaca* DW4/3-1 were grown in liquid CTT<sup>22</sup> and TS medium<sup>23</sup>, respectively, at 30 °C and 200 r.p.m. on a rotary shaker until the desired optical density was obtained. All strains of *E. coli* were grown in liquid or on solid Luria Bertani (LB)<sup>24</sup> medium. For growth on agar plates, 1.5% agarose was added to the medium before autoclaving for solidification. Cultures of antibiotic-resistant mutant strains were supplemented with kanamycin (40 µg/ml) and/or chloramphenicol (34 µg/ml) to maintain plasmid stability or inserted gene disruption constructs. A complete list of all strains used in this study is in **Supplementary Table 10**.

All chemicals and analytical standards used for the experiments were, if not stated otherwise, obtained from Sigma-Aldrich Corporation or Carl-Roth GmbH and were at least

of analytical grade. Water was obtained from an Elga LabWater Model PL 5241 (VWS Deutschland GmbH) water purification system.

Pictures of protein gels were taken with transillumination by a light box using a model D90 reflex camera (Nikon GmbH, Germany) with a 60-mm prime lens, an aperture of f/16, an ISO value of 200 and an exposure time of 1/60 s at a resolution of 12 megapixels and saved in the NEF format. Pictures of western blots were taken under daylight the same way but with an aperture of f/3.5.

All pictures of fluorescent protein gels and primuline-stained thin layer chromatography (TLC) plates were acquired in a model UViprochemi 2026 WL/UV26M (Biometra GmbH) gel documentation system. Gels were transilluminated with UV light at a wavelength of 366 nm and with an ethidium bromide filter (cutoff:  $\lambda = 580$  nm) mounted in front of the camera lens. Fluorescent TLC pictures were taken with the UV light coming from the top ( $\lambda = 366$  nm) and without a cutoff filter in front of the camera lens. The resolution of the pictures was 1.3 megapixels, and they were initially saved in the TIF format.

Cropping and adjustment of contrast and brightness to enhance the visibility of all details in the pictures and conversion into JPEG images were carried out using Lightroom 3 (Adobe Systems GmbH).

Pictures of developing *S. aurantiaca* cells on an agar surface were taken using a 1.4-megapixel Zeiss AxioCam Mrc digital camera (Carl Zeiss AG) attached to a SZH binocular (Olympus Europa Holding GmbH). Image data were acquired by the AxioVision Software (Carl Zeiss AG). The aperture was set to f/4.5, exposure time was 20 ms and JPEG was chosen as the image data format. The pictures of developing *M. xanthus* cells were recorded with a D90 reflex camera (Nikon GmbH) mounted on a Leica DM750 microscope (Leica microsystems GmbH) equipped with a 2.5 $\times$  object lens. The aperture of the transmitted light was maximally closed, the exposure time was set to 1/125 s, the ISO value was 200 and NEF was chosen as the file format. Small deviations in brightness due to fluctuating thickness of the agar were adjusted afterwards.

For quantification of fluorescent bands as well as the corresponding Coomassie blue-stained bands obtained by the ACP loading assay and the adenylation domain assay (described below), ImageJ (version 1.47) was used. To calculate a normalized fluorescence, the quotient of control to sample in the Coomassie blue-stained picture of the

SDS-PAGE gels was multiplied with the quotient of the control to the sample band of their fluorescent images.

**Starvation induced development in *M. xanthus*.** Cells were grown vegetatively to an optical density (OD<sub>600</sub>) of ~1.2 (~ $3.8 \times 10^8$  cells/ml), pelleted, washed twice in MC7 buffer<sup>25</sup> and resuspended again in MC7 medium to a cell density to  $5 \times 10^9$  cells/ml, of which 5  $\mu$ l were spotted onto TPM agar<sup>25</sup> and incubated at 30 °C for up to 120 h. Sufficient cells for a FAME analysis or a lipid extract were obtained by plating  $7.5 \times 10^9$  cells in 25 ml MC7 medium in petri dishes or  $6 \times 10^{10}$  cells in 150 ml MC7 medium in rectangular cell culture plates (25 cm  $\times$  25 cm), respectively, and incubated as mentioned above. For the sporulation assay,  $1.27 \times 10^9$  vegetative cells in 3.5 ml MC7 buffer were developed in triplicate for 72 h and 120 h in petri dishes with a diameter of 3.5 cm.

**Sporulation assay.** The developed cells were incubated at 56 °C for 2 h to inactivate vegetative cells, harvested and resuspended in 10 ml water before treating with ultrasonic sound. 50  $\mu$ l of this suspension in the case of the *elbD* mutant and 50  $\mu$ l of a tenfold dilution for all of the other strains investigated were plated on CTTYE agar<sup>26</sup> plates for germination. The plates were incubated at 30 °C for 5 d, and colonies were counted. Mean and s.d. as well as *P* values were calculated analogously to those for the FAME data (**Supplementary Note 2**). Colony numbers were normalized to the wild type, which was defined as 100%. Detection limits were defined as less than one colony in one of the triplicates relative to wild-type colonies at the given time point.

**Heterologous expression of *elbD* constructs in *E. coli* for protein purification.** Two versions of *MXAN\_1528* were heterologously expressed: A full-length version (*elbD*) was amplified using primers *elbDmx\_redom\_BamHI-1* and *elbDmx\_re\_XhoI-2* and a shortened version without the reduction domain (*elbD $\Delta$ re*) with *elbDmx\_re\_BamHI-1* and *elbDmx\_re\_XhoI-2*; both fragments were subsequently cloned into the BamHI and XhoI restriction sites of pSUMO3\_ck4 vector, giving rise to pSUMO3\_ck4\_*elbD* and pSUMO3\_ck4\_*elbD $\Delta$ re*. When induced, *elbD* and *elbD $\Delta$ re* are expressed as fusion proteins with an N-terminal His<sub>6</sub>SUMO3 tag to enhance correct folding of the protein product. The sequence of the constructs was verified by DNA sequencing of both strands. *E. coli* strain BL21(DE3) was used as an expression host. To further enhance correct folding and solubility, *elbD* and *elbD $\Delta$ re* were coexpressed with the trigger factor gene *tig* from plasmid pTf16 (ref. 27). Expression procedures were carried out according to

standard procedures (pET System Manual, Merck-Millipore KGaA). Briefly, the expression strains were inoculated 1:100 (v/v) from an overnight culture in 1 l LB medium supplemented with chloramphenicol, kanamycin and 0.25 mg/ml arabinose, grown at 30 °C and 160 r.p.m. to an optical density of ~1.2. Protein expression was induced by adding isopropyl  $\beta$ -D-1-thiogalactopyranoside (IPTG) to a final concentration of 0.1 mM. Expression was performed at 16 °C and 160 r.p.m. for 16 h.

**Heterologous expression of *elbA–E* in *E. coli* for testing *in vivo* activity.** Genes *elbA–elbE* were heterologously expressed in *E. coli* BL21(DE3) while fed with i15:0 fatty acid and were subsequently analyzed for the presence of alkyl or vinyl ethers by FAME GC/MS. Genes *MXAN\_1531*, *MXAN\_1530*, *MXAN\_1529* and *MXAN\_1527* were synthesized with codon optimization for *E. coli* at Life Technologies and provided as cloning vectors pMK-RQ\_MXAN\_1527-1531exp\_synth and pMK-RQ\_MXAN\_1530-1529exp\_synthm, whereas *MXAN\_1527* and *MXAN\_1531* on the one hand and *MXAN\_1530* and *MXAN\_1529* on the other hand were made as artificial operons in a single reading frame.

Cloning procedures were executed as follows: in the first step, *elbD* was amplified from pSUMO3\_ck4\_elbD using primers *elbDmx\_exp\_NdeI-3* and *elbDmx\_-re\_XhoI-2*, subcloned into pJet1.2/blunt (Thermo Scientific), sequenced and afterwards cloned into pCOLA\_tacI/I via restriction sites NdeI and XhoI, giving rise to pCOLA\_tacI/I\_MCSII\_MXAN\_1528exp. Genes *MXAN\_1530* and *MXAN\_1529* were directly cloned into pCOLA\_tacI/I\_MCSII\_MXAN\_1528exp via restriction sites EcoRI and SdaI, giving rise to pCOLA\_tacI/I\_MCSI\_MXAN\_1530-1529exp\_MCSII\_MXAN\_1528exp.

*MXAN\_1527* and *MXAN\_1531* were cloned into pACYC\_tacI/I using NdeI and XhoI, resulting in plasmid pACYC\_tacI\_MCSII\_MXAN\_1527\_1531. To enable *E. coli* to form branched-chain fatty acids, genes *bkdA–C* from *Photorhabdus luminescens* TT01 (ref. 28) were cloned from plasmid pCOLA\_bkd\_C into pACYC\_tacI\_MCSII\_MXAN\_1527\_1531 using SacI and PstI, giving rise to pACYC\_tacI\_MCSI\_bkdA-C\_MCSII\_MXAN\_1527\_1531.

As both plasmids have compatible origins of replication and confer different antibiotic resistances, all of the genes were expressible together in *E. coli*. Additionally, the tacI

promoter in front of the genes enabled IPTG-dependent transcription with comparable transcript numbers.

For the expression experiment plasmids, *E. coli* BL21(DE3) cells were transformed with pCOLA\_tacI/I\_MCSI\_MXAN\_1530-1529exp\_MCSII\_MXAN\_1528exp, pACYC\_tacI\_MCSI\_bkdA-C\_MCSII\_MXAN\_1527\_1531 and pET32a\_mtaA\_NdeI/XhoI in the samples and pCOLA\_tacI/I, pACYC\_tacI/I and pET32a in the controls.

Cells were grown at 37 °C overnight in Tanaka medium without IPTG. Expression experiments were performed in 1.5-ml volumes and adjusted to an OD600 of 1.0 with the following variables: medium: Tanaka or LB; IPTG concentrations: 0.05 mM, 0.1 mM or 0.4 mM; expression time and temperature: 16 h at 16 °C or 6 h at 23 °C; iso15:0 fatty acid concentration: 0.25 mM or 1 mM.

Cells were pelleted after the aforementioned expression times of 6 h or 16 h, subjected to FAME derivatization and analyzed by GC/MS as described above, and the resulting spectra were surveyed for the presence of dimethylacetals (indicative ion:  $m/z = 75$ ) and *O*-alkylglycerols (indicative ion;  $m/z = 205$ ) in general and i15:0 DMA and i15:0-OAG in particular as surrogates for the formation of alkylglycerols and 1Z-alkenylglycerols.

**Heterologous expression of *sfp* and *mtaA* constructs in *E. coli*.** The phosphotransferases Sfp from *Bacillus subtilis* and MtaA from *S. aurantiaca* DW4/3-1 were expressed in a similar way to *MXAN\_1528*, but for Sfp, the sequence for the SUMO3 tag was removed during the cloning procedure using the *Pst*I and *Mun*I restriction sites of pSUMO3\_ck5. Genomic DNA *B. subtilis* and *S. aurantiaca* DW4/3-1 were used as templates to amplify *sfp* and *mtaA*, respectively. For the *mtaA* PCR product, *Bgl*II/*Eco*RI restriction sites were used. The sequences of the constructs were verified by DNA sequencing. Expression conditions were identical to those mentioned above.

**Purification of His<sub>6</sub>SUMO3ElbD and His<sub>6</sub>SUMO3ElbDΔre.** Heterologously expressed proteins were purified from soluble fractions of cell lysates by nickel-NTA column chromatography and gel filtration chromatography. An ÄKTApurifier 10 FPLC system upgraded with a column screening kit, a sample application kit, air sensor kit and a fraction Collector Frac-950 (all from GE Corp.) was used for this purpose. All of the purification steps were monitored using SDS-PAGE<sup>29</sup> with normalized gel loading (pET System

Manual, Merck-Millipore KGaA). The pelleted cells from the protein expression were resuspended in 7 ml binding buffer (20 mM Tris-HCl 20 mM imidazole, 20% (w/v) glycerol, 0.1% (w/v) Triton X-100, pH 7.5) supplemented with 100  $\mu$ l Protease Inhibitor Cocktail Set II (Calbiochem, Merck KGaA) and 25 U/ml benzonase (Merck KGaA) and lysed by adding 10,000 U/ml lysozyme and incubating for 30 min at room temperature. After centrifugation at 15,000g for 45 min, the supernatant was filtered through a 0.45- $\mu$ M filter membrane and loaded to a 1-ml HisTrap HP column (GE corp.) and washed with 15 ml binding buffer (without Triton X-100). Recombinant proteins were eluted stepwise with 5 ml of 50 mM, 100 mM, 200 mM and 500 mM imidazole, respectively. Fractions containing the expressed proteins were pooled and concentrated to ~2 ml using Amicon ultra centrifugal filter units (Merck Millipore KGaA). Buffer exchange to gel filtration buffer (50 mM Tris-HCl, 10 mM MgCl<sub>2</sub>, 500 mM NaCl, 20% (w/v), pH 7.5, concentrated again to ~1 ml and treated with 60 U SUMO protease 2 (LifeSensors Inc.) in each case. For gel filtration, 500  $\mu$ l of the SUMO protease digestion was separated on a Superdex 200 10/300 GL column (GE Corp.) and separated into 1-ml fractions at a constant flow rate of 0.3 ml/min. Again, fractions containing either ElbD or ElbD $\Delta$ re were pooled, and buffer was exchanged to protein storage buffer (50 mM Tris-HCl, 10 mM MgCl<sub>2</sub>, 50% (w/v) glycerol, pH 7.5) and concentrated again using a Vivaspin500 Ultra Centrifugal filter units (Sartorius AG) to ~100  $\mu$ l (ElbD) and ~200  $\mu$ l (ElbD $\Delta$ re). Protein concentrations were 0.6  $\mu$ g/ $\mu$ l for ElbD $\Delta$ re and 4.0  $\mu$ g/ $\mu$ l for ElbD.

**Protein fractionation for *in vitro* acyltransferases assay.** Solubilized membrane fractions of *E. coli* cells expressing ElbD were used for this assay. The preparation of this fraction was performed very similarly to a method described in ref. 30. As a control, proteins from equally treated *E. coli* cells bearing only the empty expression vector were used.

Protein expression and cell lysis was carried out as described above. Unlysed cells were pelleted by centrifugation at 8,000g for 15 min at 4 °C. The supernatant was then again subjected to ultracentrifugation at 105,000g for 90 min at 4 °C to pellet the membranes and inclusion bodies of the lysed cells. The pellet was then resuspended in a buffer containing 100 mM Tris-HCl, pH 8.0, 300 mM NaCl, mixed with an equal amount of 1% sodium lauroyl sarcosinate, incubated for 20 min at room temperature under agitation and centrifuged again at 105,000g for 90 min at 4 °C to remove indissoluble protein. Protein

concentrations were 1.1 mg/ml in the control preparation and 0.8 mg/ml in the sample preparation.

**Purification of His<sub>6</sub>Sfp and His<sub>6</sub>SUMO3MtaA.** For His<sub>6</sub>Sfp, purification was performed as mentioned above, but fractions from the nickel-NTA affinity chromatography were directly buffer exchanged to a storage buffer containing 50 mM 2-(4-(2-hydroxyethyl)-1-piperazinyl)-ethanesulfonic acid (HEPES), pH 7.6, 100 mM NaCl, 10% glycerol after combination of protein containing fractions and concentration. 4.1 mg of protein were obtained from 500 ml expression culture.

His<sub>6</sub>SUMO3MtaA was purified using the Protino-Kit (Macherey-Nagel GmbH) according to the manufacturer's instructions and concentrated, and the buffer was exchanged as described for His<sub>6</sub>Sfp, yielding 2.3 mg of protein from a 500-ml expression culture.

**Fluorescent labeling of ACP domain using a CoA analog.** BODIPY-CoA analogs were synthesized from BODIPY FL maleimide (Life Technologies) and coenzyme A as described previously<sup>31</sup> and *in vitro* labeling of ACP was performed similarly to a published procedure<sup>31</sup>. In short, 1 µl of ElbD or ElbDΔre was incubated overnight at 30 °C in a mixture of 5 µl 10× reaction buffer (750 mM 2-(*N*-morpholino)ethanesulfonic acid (MES), 100 mM MgCl<sub>2</sub>, 1,500 mM NaCl, pH 6.0), 1 µl of ~200 µM BODIPY-FL-CoA solution and 1 µl of Sfp solution filled up to 50 µl with water. After incubation, proteins were precipitated with 12.5 µl of 3 M trichloroacetic acid (TCA), pelleted, washed with water and pelleted again. After removal of the supernatant, the pellets were dried and redissolved in 10 µl 1 M Tris-HCl, pH 6.0, and 5 µl of 3× SDS-PAGE loading buffer at 95 °C for 5 min. Proteins were resolved on an 8% sodium dodecyl sulfate polyacrylamide gel (SDS-PAGE), and fluorescence<sup>31</sup> was recorded as stated above with an aperture of f/1.4, a focal length of 95 mm and an exposure time of 15 s.

**Acyl-ACP loading assay.** The activity of the adenylation domain of ElbD has been determined by testing the ability of its shortened version, ElbDΔre, to load an azido-labeled fatty acid on its own ACP-domain, in a procedure similar to that published for the visualization of lipoproteins<sup>32</sup>. In the first step, ElbDΔre was phosphopantetheinylated by mixing 8.3 µl protein solution with 5 µl 50 mM Tris-HCl buffer, 10 mM MgCl<sub>2</sub>, pH 7.5, buffer, 0.5 µl 10 mM Coenzyme A solution and 0.5 µl of a 10 µM MtaA solution; filled up to 50 µl with water; and incubated at 30 °C for 4 h. Afterward, 0.5 µl of a 100 mM solution of ATP (ATP) and 0.5 µl of a 10 µM of 15-azidopentadecanoic acid (az15:0) in DMSO

was added, followed by a further incubation at 30 °C for 5 h. To remove unreacted az15:0, the reaction mixture buffer was exchanged to 50 mM triethylamine (TEA), 150 mM NaCl, 0.1% (w/v) sodium dodecyl sulfate using PD SpinTrap G25 columns (GE Corp.). Acylated protein was fluorescently labeled by adding 3 µl of a 10-mM dibenzcyclooctyne-Fluor 488 (Fluor 488-DBCO) (Jena Bioscience GmbH) in dimethyl sulfoxide solution and incubating overnight at 37 °C. Proteins in the reaction mixture were precipitated as described in ref. 33, washed twice with 500 µl methanol and redissolved in 50 µl 1× SDS-PAGE loading buffer. 20 µl was resolved on a 10% SDS-PAGE. Pictures of the fluorescence were acquired as mentioned above with a focal length of 96 mm, an aperture of f/5.6 and an exposure time of 1 s.

***In vitro* acyltransferase assay.** The AT assay was carried out under the following conditions: 100 mM Tris-HCl, pH 7.5, 10 mM MgCl<sub>2</sub>, 1 mM ATP, 600 µM acyl donor (**Supplementary Note 2**), 150 µM of acyl acceptor (**Supplementary Note 2**) and 1 mg/ml BSA in a total volume of 100 µl. Incubation was performed at 30 °C for 45 min. Each sample contained 10 µg of tested protein. A sample without acyl donor served as a control. Lipids were extracted from the assay by the method described in ref. 34. In the samples in which monoacylglycerophosphates were used as test substrates, 10 µl of 10 M hydrochloric acid was added before the extraction procedure to protonate those lipids for a higher hydrophobicity. The lipids were dissolved in a mixture of dichloromethane:methanol:water 65:35:8 (v/v/v) when monoacylglycerophosphoethanolamines were used and dichloromethane:methanol:acetic acid 40:10:1 (v/v/v) when the samples contained monoacylglycerophosphates. Those samples were subjected to HPLC/MS analysis with a similar setup as described in **Supplementary Note 2** except that the gradient started at 30% B, was increased to 99% in a linear manner over 30 min and held for 7 min before reequilibration. HPLC/MS chromatograms were checked for *m/z* 671.5 in the positive ion mode and 626.5 in the negative ion mode, which would indicate incorporation of d7-i15:0 into PE(0:0/i15:0) or PA(0:0/i15:0), respectively.

#### Accession codes

GenBank: Sequences of expression plasmids pSUMO3\_ck4, pSUMO4\_ck5, pMK-RQ\_MXAN\_1527-1531exp\_synth and pMK-RQ\_MXAN\_1530-1529exp\_synth are

available under accession numbers KJ633124, KJ633125, KJ633122 and KJ633123, respectively.

### Acknowledgments

The authors are grateful to M. Ring for the identification of the *elb* operon; O. Schimming for providing the phosphopantetheinyl transferases; C. Kegler for providing expression plasmids pSUMO3\_CK4, pSUMO3\_CK5, pCOLA\_tacI/I and pACYC\_tacI/I; S. Fuchs for the MALDI-MS measurements; and A. Perèz for providing acyl donors. H.B.B. is grateful to the German Research Foundation (DFG) for an Emmy Noether fellowship that initiated this work.

### Author contributions

H.B.B. conceived the work, W.L. and T.A. designed and performed the myxobacterial sporulation assay, and W.L. designed and performed all of the other experiments. Molecular modeling and ligand docking experiments were performed by K.A.J.B. H.B.B. and W.L. wrote the paper.

### Competing financial interests

The authors declare no competing financial interests.

### Additional information

Supplementary information is available in the online version of the paper. Reprints and permissions information is available online at <http://www.nature.com/reprints/index.html>. Correspondence and requests for materials should be addressed to H.B.B.

## **6.2.5 Supplementary Information**

**A multifunctional enzyme is involved in bacterial ether lipid biosynthesis**

Wolfram Lorenzen, Tilman Ahrendt, Kenan A.J. Bozhüyük, Helge B. Bode

**Supplementary Results**

**Supplementary Figure 1 | (next page) Phenotypes of *elbA*, *B*, *D*, *E* disruption mutants.**

**a)** Microscopic plan view of developing *M. xanthus* cells with results of sporulation assay (italics numbers within 72 h images: mean % and standard deviation of colony forming units relative to wild type; n=3) at 72 / 120 h after starvation induced fruiting body formation (scale bars= 500  $\mu$ m). Values greater than 10 % were rounded for the sake of readability. **b)** Changes of i15:0-OAG (dark grey) and i15:0-DMA (light grey) in mutant vegetative and developed cells compared to wild type (mean % and standard deviation; n=3). Asterisks indicate level of significance for the respective analyte (\* p<0.05, \*\* p<0.01, \*\*\* p<0.001). **c)** Microscopic plan view of aggregating *S. aurantiaca* cells. Sporulation experiments of *S. aurantiaca* were not feasible as strain DW4/3-1 does not form fruiting bodies under our laboratory conditions. However, note the „spot“ like aggregate of the *elbD* mutant in comparison to the „ring“ like aggregates of the wild type (scale bars= 1000  $\mu$ m). **d)** Changes of i15:0-OAG (dark grey), i15:0-DMA (light grey), 15:0-OAG (dotted) and 16:1-OAG (shaded) in mutant vegetative cells compared to wild type (mean % and standard deviation; n=3). Asterisks indicate level of significance for the respective value referred to wild type result (\* p<0.05, \*\* p<0.01, \*\*\* p<0.001). See Supplementary Data Set 1, Supplementary Table 2 and 3 for full FAME patterns, results of sporulation assay and statistics. n.a.: data not available.

**Supplementary Figure 2 | (next page) *elbA-E* homologues in all sequenced myxobacteria**

The operon structure of *elbA-E* orthologous in myxobacteria is shown. *elbD* and *elbE* are in all but one case overlapping, *elbB* and *elbC* are located either close to *elbD* and *elbE* upstream or can be found somewhere else in the genome. *elbA* is more separated from *elbB-E* or absent in some of the genomes. This provides further evidence for the hypothesis that the decreased ether lipid formation in *elbB* insertion mutants is rather due to diminished *elbD* expression by polar effects than due to an involvement of *elbB* and *elbC* in ether lipid formation (Supplementary Figure 1). For further details see Supplementary Data Set 2. Italic numbers indicate gene length and length between genes in base pairs respectively.

**Supplementary Figure 3 | EI-MS chromatograms of *O*-alkylglycerols from various myxobacteria.**

**a)** Excerpt of GC-MS total ion chromatograms of different myxobacterial wild type strains from whole cell fatty acid methyl esters. Asterisks indicate signals of non-ether lipid molecules. blue: *Sorangium cellulosum* So ce377; black: *Cystobacter sp.* SBCb004; green: *Myxococcus xanthus* DK897; red: *Sorangium cellulosum* So ce56 **b-f)** Electron impact mass spectra of 14:0-, i15:0-, i16:0-, 16:1- and 16:0-OAG-bisTMS respectively. Spectra were interpreted as described previously<sup>4</sup>.

**Supplementary Figure 4 | Lipid composition of *M. xanthus* and its *elbD* mutant.**

Primuline-stained TLC plates of lipid extracts from vegetative *M. xanthus* cells (0 h) and those developed for 24 h, with resolved phospholipids (**a**) and neutral lipids (**b**). NL, neutral lipids; PE, glycerophosphoethanolamine; PG, glycerophosphoglycerol; LysoPI, lysophospholipid; MADAG, alkyldiacylglycerol; TAG, triacylglycerol; DAG, diacylglycerol; MAMAG, monoalkylmonoacylglycerol; MAG, monoacylglycerol. Note the loss of the MADAG spot in the lipid extract of *elbD* after 24 h of development.

### Supplementary Figure 5 | 2-acyl-lyso-PEs are formed by *M. xanthus*

Extracted ion chromatograms of lysophosphatidylethanolamines from a freshly prepared DK1622 lipid extract **a**), an extract stored for a prolonged time **b**) and a 1-acyllyso-PE standard from Sigma **c**) with the typical ~9:1 molar ratio of *sn*-1 to *sn*-2 isomer<sup>35</sup>. Mass spectra **d**) and **e**) show that in loss of the polar headgroup is favored over the loss of water in the case of the *sn*-2 isomer whereas it is vice versa in the case of the *sn*-1 isomer. The differing retention times derive from the instance that different HPLC-MS systems and gradients were used.

### Supplementary Figure 6 | (previous page) Biochemical characterization of ElbD.

**a)** Full gel image of Figure 2c. Enzymatic labeling of ElbD with fluorescent BODIPY-FL Coenzyme A with (+) and without (-) Sfp. Average normalized fluorescence intensity is 5.3× above control (n = 2; R = 2.2-8.4). **b)** Full gel image of Figure 2d. F488-DBCO labeling of az15:0 loaded onto phosphopantetheinylated ACP domain of ElbD $\Delta$ re with (+) and without (-) az15:0 in the assay. Average normalized fluorescence intensity is 4.7× above control (n = 2; R = 2.8-6.6). C: coomassie stain; FL: fluorescence; OL: overlay. Numbers indicate apparent molecular weight in kD. **c)** Phylogenetic tree (PHYML) of trimmed sequences from long chain acyltransferases from various organisms that cluster well according to their specificity. 2-LPEAT: 2-lysophosphatidylethanolamine acyltransferase; AGPAT: 1-acylglycerolphosphate acyltransferase; GPAT: glycerolphosphate acyltransferase; for details see Supplementary Figure 9 and Supplementary Data Set 3 **d)** *In-silico* docking of 2-i15:0-lysophosphatidylethanolamine into the acyltransferase domain of ElbD. Grid shows electron cloud of the substrate. Note the interaction between the hydroxyl group in the *sn*-2 position of the glycerol moiety with the putative charge relay system of Asp170 and His165.

**a****b****c****d****e**

**Supplementary Figure 7 | (previous page) Truncated translation products of ElbD when expressed in *E. coli*.**

SDS-PAGE of Ni-NTA affinity chromatography fractions (3-8) of His<sub>6</sub>SUMO3ElbD (**a**) and His<sub>6</sub>SUMO3ElbDΔre (**c**) (1: pellet fraction; 2: soluble fraction). SDS-PAGE of SEC fractions (2-14) of the respective Sumo2 protease treated Ni-NTA chromatography fractions of ElbD (**b**) and ElbDΔre (**d**) (1: pellet fraction). **e**) Coomassie stained SDS-PAGE (left), western blot (center) and merge (right) of various Nickel-NTA affinity chromatography fractions. Co-eluting bands are products of flawed His<sub>6</sub>SUMO3ElbD translation. Numbers indicate apparent molecular weight. Additional bands with smaller molecular weight than the target protein proved to be truncated translation products as shown by western blot and peptide mass finger print (see Supplementary Table 12-16). C: coomassie stain; WB: western blot; OL: overlay

**Supplementary Figure 8 | Modeling of A- and AT-domain of ElbD**

**a)** Superposition of the ElbD A-Domain (blue) homology model (RMSD: 1.7 Å) modelled on the 1.9 Å crystal structure of PheA from the gramicidin synthetase from *Bacillus brevis* (red) **b)** Superposition of a 364aa stretch comprising the ACP and AT domain of ElbD modelled on the crystal structure of the stromal GPAT from *Curcubita moscata* (RMSD: 1.4 Å).

### Supplementary Figure 9 | Docking of fatty acyl substrate in ElbD A-Domain.

Ribbon representation of ElbD A-domain (top view; blue: N-terminal subdomain; green: C-terminal subdomain) with docked AMP (CHEMPLP-score: 43.34) and iso15:0 (CHEMPLP-score: 65.24). The active site is located in the cleft between the two subdomains. Magnified view (bottom view) of the binding pocket shows hydrophobic (green) and hydrophilic (purple) surfaces. Gly364 provides the necessary space to access the hydrophobic tunnel for long chain fatty acids, Phe226 is limiting the maximal length and His253 is necessary for the binding of the fatty acid by interacting with its carboxy moiety.

**Supplementary Figure 10 |(previous page) Phylogenetic analysis of acyltransferase domains with different substrate specificities.**

Unrooted cladogram of phylogenetic analysis of acyltransferase domains from various sources (Supplementary Table 9) derived from a trimmed MAFFT alignment (Supplementary Data Set 3). Acyltransferases with various preferences concerning the hydroxyl functions of the glycerol phosphate acceptor (*sn-1* or *sn-2*, acylation or no acylation) cluster within distinct branches, whereupon the acyltransferase domains of the ElbD homologues forms its own branch with 2-lysophosphatidylethanolamine acyltransferase (2-LPEAT) domains that exhibit a specificity towards 2-acylglycerolphosphoethanolamine. Numbers indicate distance given in substitutions per site. Asterisks indicate acyltransferases with experimentally determined substrate specificities. GPAT from *C. muscata* and AT-domain of ElbD from *M. xanthus* are highlighted in bold. For details concerning the alignment see Supplementary Data Set 3 Supplementary Table 9. 2-LPEAT: 2-lysophosphatidylethanolamine acyltransferase; AGPAT: 1-acylglycerolphosphate acyltransferase; GPAT: glycerolphosphate acyltransferase.

**Supplementary Figure 11 | Docking of putative ElbD substrate in acyl transferase model.**

Ribbon representation (left) of ElbD AT domain with docked 2-i15:0-lysophosphatidylethanolamine (CHEMPLP-score: 71.75). Magnified view (right) of 2-i15:0-lysophosphatidylethanolamine docked into the putative binding pocket of the AT domain (green and purple hydrophobic and hydrophilic surfaces respectively). The docking experiments for the ElbD AT domain with 2-isopentadecanoylphosphatidylethanolamine proposed interactions with H(X)<sub>4</sub>D motif of the amino acids Asp170 and His165 which are invariant in homologues sequences<sup>36</sup> forming a putative charge relay system that can abstract the hydrogen from the free 1-hydroxy group, which in turn enables the attack of this hydroxyl oxygen at the carbonyl carbon of the acyl donor during the ester formation. This arrangement resembles the active site of serine proteases and epoxide hydrolases and was also postulated for acyltransferases<sup>37</sup>.

**Supplementary Figure 12 | Formation of i15:0 aldehyde is abolished in *elbD* mutants.**

Total ion chromatograms of wt (dashed) and *elbD* (solid line) cells of *M. xanthus* (**a**) and *S. aurantiaca* (**b**). c) i15:0 aldehyde was identified by comparing mass spectra and chromatograms of  $d_9$ -i15:0-PFB oxime (left spectrum) with i15:0-PFB oxime (right spectrum) obtained from analyzing metabolically labeled cells as described in methods section; solid line: unlabeled sample; dashed line: sample from  $d_{10}$ -Leucine fed cells.

### **Supplementary Figure 13 | (previous page) ElbD-like homologues with similar domain architecture outside the order Myxococcales**

Examples of ElbD homologues found by BLAST P search in decreasing order of homology. Note the broad range of clades, in which ElbD like homologues are detectable. Sequence identity is between 28-33%. Presence of plasmalogens was confirmed for *Fusobacterium mortiferum* (*Sphaerophorus rediculosis*)<sup>38</sup> while *Fusobacterium ulcerans* is an important pathogen found in tropical ulcers<sup>39</sup>. Etherlipids have also been identified from various sponges<sup>40,41,42</sup> in which Poribacteria are frequently encountered as endosymbionts. However, a clear fatty acyl-CoA reductase domain homologue could not be detected for the organisms other than *Candidatus Poribacteria*. Re: fatty-acyl-CoA like reductase domain; A: acyl-CoA synthetase domain; T: acylcarrier protein / thiolation domain; AT: acylglycerolphosphate acyltransferase domain.

**Supplementary Table 1** | FAME-GC-MS data of vegetatively grown DW4/3-1 cells in per cent of total fatty acid methyl esters. Averages and standard deviations were calculated from three independent biological samples. Values following less-than sign indicate analytes below detection limit. Colors indicate level of significance (green:  $p < 0.05$ ; yellow:  $p < 0.01$ ; magenta:  $p < 0.001$ ). For details see method section. DMA: Vinyl ether derived dimethylacetals; OAG: alkyl ether derived *O*-alkylglycerols.

pCKT7A1_attB_blunt-2	TTTCGCGACATGGAGGACT	cloning primer for pWL02zeo_att

Plasmid Name	Function	Reference
pJet1.2/blunt	cloning vector	Thermo Scientific
pCR@II-TOPO@	cloning vector	life technologies inc.
pCRII-TOPO MXAN1527	suicide plasmid, pCRII-TOPO carrying internal fragment of MXAN_1527	This study
pCRII-TOPO MXAN1530	suicide plasmid, pCRII-TOPO carrying internal fragment of MXAN_1530	This study
pCRII-TOPO MXAN1531	suicide plasmid, pCRII-TOPO carrying internal fragment of MXAN_1531	This study
pMRMXAN_1528ko-2	suicide plasmid, pMR06kan carrying internal fragment of MXAN_1528	This study
pMR06kan	cloning vector, Km <sup>r</sup>	72
pMR08kanT	cloning vector, harbouring RP4 <i>oriT</i> , Km <sup>r</sup>	72
pMR10_kanT	cloning vector, harbouring RP4 <i>oriT</i> , Km <sup>r</sup>	This study
pWL_STIAU2023ko	suicide plasmid, pMR10_kanT carrying internal fragment of STAU_2305	This study
pWL_STIAU2025ko	suicide plasmid, pMR10_kanT carrying internal fragment of STAU_2304	This study
pMRSTAU_2302ko	suicide plasmid, pMR08_kanT carrying internal fragment of STAU_2302	This study
pSUMO3_ck4	expression plasmid	This study
pSUMO3_ck4_elbD_delta_re	expression plasmid, for ElbD AA547-1470, N-terminal His <sub>6</sub> and SUMO-tag	This study
pSUMO3_ck4_elbD	expression plasmid, for ElbD, N-terminal His <sub>6</sub> and SUMO-tag	This study

pSUMO3_ck5	expression plasmid	This study
pSUMO_mtaA	expression plasmid, for MtaA, N-terminal His <sub>6</sub> and SUMO-tag	This study
pSUMO_sfp	expression plasmid, for Sfp, N-terminal His <sub>6</sub> -tag	This study
pTf16	expression plasmid, for coexpression of the chaperone coding <i>tig</i> gene	TAKARA BIO INC.
pET32a	expression plasmid, T7 promotor, amp <sup>r</sup>	Novagen
pCOLA_tacI/I_MCSI_MXAN_1530-1529exp_MCSII_MXAN_1528exp	expression plasmid for MXAN_1530, MXAN_1529, MXAN_1528	This study
pACYC_tacI_MCSI_bkdA-C_MCSII_MXAN_1527_1531	expression plasmid for MXAN_1527, MXAN_1531	This study
pET32a_mtaA_NdeI/XhoI	expression plasmid for MtaA	73
pCOLA_tacI/I	expression plasmid for two inserts, colA oriR, two mcs with tacI promotors, Km <sup>r</sup>	This study
pACYC_tacI/I	expression plasmid for two inserts, pACYC oriR, two mcs with tacI promotors, Cm <sup>r</sup>	This study
pMK-RQ_MXAN_1527-1531exp_synth	cloning vector containing MXAN_1527 and MXAN_1531 codon optimized for <i>E. Coli</i>	This study/life technology
pMK-RQ_MXAN_1530-1529exp_synth	cloning vector containing MXAN_1530 and MXAN_1529 codon optimized for <i>E. Coli</i>	This study/life technology
pWL02zeo_att	expression vector for <i>M. xanthus</i> , Zeo <sup>r</sup>	This study
pWL02zeo_MXAN_1528exp	expression vector for MXAN_1528	This study
pWL02zeo_MXAN_2027exp	expression vector for STAUR_2302	This study

---

**Supplementary Table 11** | Total weight in mg of lipid extracts from *M. xanthus* DK1622 and TLC fractions derived thereof.

	Total Extract	Lysophospholipid Fraction	Phosphatidylglycerol Fraction	Phosphatdiylethanolamine Fraction	Neutral Lipid Fraction
wt veg I	2.2				
wt veg II	2.3	1.2	3.1	2.4	5.4
wt veg III	2.1

## Supplementary Note 1: Molecular Biology Methods

### General biomolecular procedures

Polymerase chain reaction, agarose gel electrophoresis, restriction enzyme digestion, DNA transfer into *E. coli*, plasmid isolation, protein gel electrophoresis and western blotting were carried out by established procedures<sup>74</sup>, whereas anti-His<sub>6</sub> PentaHis<sup>TM</sup> monoclonal antibodies (Qiagen NV) and anti-mouse IgG alkaline phosphatase antibody conjugates (Sigma-Aldrich Corp.) were used as the respective primary and secondary antibody.

Tryptic protein digestion for peptide mass fingerprint (PMF) was done using a published protocol<sup>75</sup>. Sample preparation, instrumentation, acquisition of mass spectra and MS data analysis is described elsewhere<sup>76</sup> except that the obtained MGF-files were compared with an *in-silico* digest of His<sub>6</sub>SUMO3ElbD using biotools 3.0 (Bruker Daltonics). The query sequence is accessible in Supplementary Table 12. Supplementary Tables 13-16 contain the matched peptide sequences of the PMF analysis of bands encircled in Supplementary Figure 5e. Those reveal additional bands in Supplementary Figure 5a-d as C-terminally truncated translation products.

All primers used for this study were designed in house utilizing either Vector NTI® (life technologies inc.) or Geneious<sup>TM</sup> (Biomatters Ltd)<sup>77</sup> and were finally obtained from Sigma- Aldrich.

The construction of gene disruption vectors for *M. xanthus* were achieved by cloning internal PCR fragments of target genes into pCR®II-TOPO® plasmids using TOPO TA Cloning® Kit Dual Promotor (life technologies inc.) according to manufactures instructions. Plasmid DNA isolation, genomic DNA isolation and DNA extraction from agarose gels was performed using the GeneJET<sup>TM</sup> Plasmid MiniPrep Kit (Thermo Scientific corp.), GeneJET<sup>TM</sup> Gel Extraction Kit (Thermo Scientific corp.) and Genra Puregene Yeast/Bact. Kit B (Qiagen NV) respectively. Protein quantification was performed with Roti®-Quant (Carl Roth GmbH).

DNA Sequencing was carried out by Seq-IT GmbH & Co. KG (Kaiserslautern, Germany). For a complete list of primers and plasmids used in this study see Supplementary Table 10.

Plasmid pMR10kanT was obtained by the following procedure: Plasmid pMR06kan<sup>72</sup> was amplified using primers kan-BgIII-BclI-1 and kan-PauI-PaeI-NcoI-2. The resulting

fragment was then used in a second round of PCR with pMR06kan as a template. After incubating the PCR mixture with *DpnI* to degrade the template, the mixture was introduced into *E. coli* JM109 by electroporation, yielding an intermediate plasmid called pMR09kan which now contained an excisable kanamycin cassette. From this plasmid, a PCR product containing the kanamycin resistance gene was generated using primers kan\_BglII-1 and kan\_PauI-2. This PCR product was ligated into pMR06tetT after excision of its tetracycline resistance gene using restriction enzymes *BglII* and *PauI* giving rise to pMR10kanT so that a plasmid for biparental conjugation was available.

pMR06tetT was obtained by the following steps: A tetracycline resistance gene (*tetA*) was amplified from pCOM9<sup>78</sup> with primers tetCOM\_PauI-1 and tetCOM\_BglII-2. Another 1.5 kb fragment containing the origin of replication and the *lacZα* gene with the multiple cloning site was amplified from pUC18 with primers pUCorilac\_PauI-1 and pUCorilac\_BglII-2. Both fragments were digested with *PauI* and *BglII* and ligated to give rise to cloning vector pMR06tet. To obtain a mobilizable vector similar to pMR08kanT<sup>72</sup>, new restriction sites were introduced by amplifying most of pMR06tet with primers orilac\_BcuI-1 and orilac\_XhoI-2. The RP4/RK2 oriT was obtained from pCOM9 with primers oriT\_SallI-1 and oriT\_XbaI-2. Both PCR products were digested and ligated, resulting in plasmid pMR06tetT.

Cloning of dual promoter vectors pCOLA\_tacI/I and pACYC\_tacI/I for heterologous expression in *E. Coli* was done in the following way: In a first step the NheI site of pCOLADuet-1 (Merck/Novagen) was deleted by a PCR using the primers pCOLA-NheI\_for and pCOLA-NheI\_rev. The PCR product was ligated leading to a single base deletion in the former NheI site and resulting in the new vector pCOLA-NheI. The annealed oligos tacI\_NcoI\_up and tacI\_NcoI\_dw were cloned into the *NcoI/EcoRI* sites of pCOLA-NheI resulting in the vector pCOLA\_tacI-NheI. In a second promoter introduction step the annealed oligos tacI\_up and tacI\_dw were cloned into the *PstI/NdeI* sites of pCOLA\_tacI-NheI resulting in the final vector pCOLA\_tacI/I harboring two tacI promoters driving the expression of potentially two cloned genes. In order to use the vector pACYCDuet-1 in a similar manner to pCOLA tacI/I independently of the T7 RNA polymerase the NheI site of the vector was deleted by amplifying the vector using pACYC-NheI\_for and pACYCNheI\_rev thereby deleting one nucleotide of the NheI site and the NheI site at that location. The PCR product was ligated leading to pACYC-NheI. The 896

bp fragment of a MluI/AvrII digest of pCOLA\_tacI/I was cloned into the MluI/AvrII site of pACYC-NheI resulting in the final vector pACYC\_tacI/I.

Vector pWL02zeo\_att is a derivative of pCK\_T7A1\_attB, that was described previously<sup>79</sup>. It consists of a ligated PCR product obtained by using primers pCKT7A1\_attB\_blunt-1 and pCKT7A1\_attB\_blunt-2 and plasmid pCK\_T7A1\_attB. It enables the expression of genes in *M. xanthus* under the control of the constitutive T7A1 promoter via integration into the genome using the MX8 phage attachment site. Plasmids pWL02zeo\_MXAN\_1528exp and pWL02zeo\_MXAN\_2027exp were constructed by direct cloning of the PCR products obtained with primers STAUR\_2302\_NdeI-1, STAUR\_2302\_EcoRI-2 and MXAN1528\_NdeI-1, MXAN1528\_BamHI-2 respectively. Inserts were verified by sequencing.

## **Construction of gene disruption and complementation mutants in *M. xanthus* and *S.***

### ***aurantiaca***

For construction of myxobacterial gene disruption and complementation mutants the respective constructs were transferred into *M. xanthus* by electroporation<sup>80</sup> or *S. aurantiaca* by biparental conjugation using established protocols<sup>81,72</sup>. The verification of the mutants was done by amplifying the integration sites from isolated genomic DNA using construct and genome specific primers<sup>25</sup>.

## **Supplementary Note 2: Chemical analysis methods**

### **Preparation of lipid extracts from bacteria**

Lipid extracts of vegetative and developed *M. xanthus* cells were obtained by the method of Bligh and Dyer<sup>34</sup>. Pellets from three independent samples from vegetative cultures and after 24 h of starvation induced development were resuspended in 2 ml of water and mixed with 5 ml of methanol and 2.5 ml of DCM. After incubation for 20 minutes at 30 °C under agitation, phase separation was induced by addition of 2.5 ml water and 2.5 ml DCM. The lower phase was removed and cells were extracted again with 3.5 ml DCM. Combined DCM phases were filtered through solvent resistant filters with a pore size of 0.22 µm and

evaporated for determination of the total lipid mass. Amounts of lipid extracts and lipid fractions obtained by preparative TLC (see below) are depicted in (Supplementary Table 11).

### **Fractionation of lipid extracts using preparative thin layer chromatography (TLC) and analytical thin layer chromatography**

For the in-depth analysis of the bacterial extracts, the three replicate biological samples were pooled and 100 µl of a solution of 10 mg/ml bacterial extract was applied per cm of the starting line of a predeveloped 200 x 200 x 2 mm silica gel 60 plates with glass backing (Merck Millipore KgaA). Separation of lipid extracts was performed using a phospholipid (PL) eluant consisting of chloroform:methanol:water 95:35:5 (v/v/v). Assignment of lipid fractions was done with genuine lipid standards which were 3-*n*-lysophosphatidylethanolamine from egg yolk for the lysophospholipid fraction, 1,2-dipalmitoyl-*sn*-glycero-3-phosphoethanolamine, for the phosphatidylethanolamine fraction, rac-1,2-distearoylglycerol, for the phosphatidylglycerol fraction and glyceryl tristearate for the neutral lipid fraction. After chromatographic separation and evaporation of the eluant, lipids were visualized by spraying with 50 mg/L primuline solution in acetone:water 80:20 (v/v) and subsequent examination under UV-light<sup>82</sup>. Fluorescent bands were scratched off, extracted three times with chloroform/methanol 1:2 (v/v), each time with sonication for 15 minutes. Combined extracts were filtered through solvent resistant 0.45 and 0.22 µm membrane filter units and the solvent was evaporated for determination of dry weight (Supplementary Table 11). Neutral lipids were fractionated in an analogous way, except that the neutral lipid fraction from the previous step was used as the starting material and a mixture of hexane:diethylether:acetic acid 80:20:1 (v/v/v) was used as the eluent to resolve the lipids. 1-Stearoyl-rac-glycerol, rac-1,2-distearoylglycerol, and glyceryl tristearate were used as standards. Analytical TLC was performed the same way but aluminium backed 200 x 200 x 0.2 mm silica 60 plates (Merck Millipore KgaA) were used and lipid extract or lipid fraction equivalent to 100 µg was spotted on the starting lane as a 0.5 cm band each time. Pictures were taken after primuline staining as described above with a focal length of 11mm, an aperture of f/16 and an exposure time of 5 s.

## **Determination of fatty acid methyl acid (FAME) patterns and neutral lipid composition in bacteria, lipid extracts and fractions thereof**

All GC-MS analysis were conducted on a 7890A model gas chromatograph (Agilent Technologies inc.) equipped with a CTC PAL Combi XT autosampler (CTC analytics AG) and coupled to a Series 5975C mass selective detector (Agilent Technologies inc.). A DB5ht column (Agilent Technologies inc.) with a length of 30 m, an inner diameter of 0.25 mm and a stationary phase of 0.1  $\mu\text{m}$  in strength was used for the separation of the analytes.

The derivatization procedure as well as the temperature program and the data analysis workflow for both, the fatty acid methyl acid analysis<sup>83</sup> and neutral lipid analysis<sup>6</sup> were performed as described. Briefly to obtain fatty acid methyl esters, 1 mg of total lipid extract, TLC fraction of lipid extracts or a dried pellet of  $7.5 \times 10^9$  cells were used as the starting material, incubated over night at 56 °C in a mixture of toluol:methanol:sulphuric acid 50:50:2 (v/v/v) for complete methanolysis. Afterwards, a solution of 400  $\mu\text{l}$  of 0.5 M ammoniumhydrogencarbonate and 3 M potassiumchloride was added. After phase separation, 75  $\mu\text{l}$  of the fatty acid methyl ester containing upper phase was transferred into a glass vial and 25  $\mu\text{l}$  of N-methyl-N-(trimethylsilyl) trifluoroacetamide (MSTFA) was added after which another 30 min incubation at 37 °C followed.

Individual detection limits for analytes not detected in a sample were calculated by dividing the peak area of the least abundant analyte by the sum of the peak areas of all analytes. Levels of significance between the individual analytes from the mutant samples compared to the wild type samples were calculated in the following way: A Welch's t-test was applied on the triplicate results of the respective mutant and wild type sample in order to obtain the t value using Excel's "T.TEST" function (two-tailed, heteroscedastic). The degrees of freedom were calculated by the Welch-Satterthwaite equation. The p-value was obtained by subtraction of the result from the T.DIST.2T function from<sup>1</sup>.

### **Detection of i15:0 aldehyde in *M. xanthus* and *S. aurantiaca* cells**

Aldehydes were detected after their derivatization to the corresponding *O*-(2,3,4,5,6-pentafluorobenzyl)-oximes as described by Wichard *et al.*<sup>16</sup>. About  $7.5 \times 10^9$  cells of vegetatively grown cells were harvested washed ones with purified water and resuspended in 1 ml of a solution containing 50 mM of *O*-(2,3,4,5,6-pentafluorobenzyl)-

hydroxylaminhydrochloride (PFBHA) in 10 mM Tris-HCl (pH 7.5) plus 10  $\mu$ l benzaldehyde in hexane (1:1000 (v/v)) as the first internal standard. Cells were disrupted by treatment with ultrasound for 3 min after the addition of glass beads followed by an incubation for 2 h at 30 °C under agitation. Afterwards, 30  $\mu$ l of PFB-undecanal (0.1 mg/ml) were added as a second internal standard. 3 ml of hexane and 0.5 ml of methanol were added, mixed and phase separation was achieved by centrifugation. 3 ml of the upper phase was withdrawn, dried under reduced pressure and dissolved in 80  $\mu$ l hexane and 20  $\mu$ l of MSTFA. After an additional incubation for 1 h at 57 °C samples were analyzed by GC-MS using the following parameters: sample volume: 1  $\mu$ l; inlet temperature: 250 °C; gas flow: 1ml/min; temperature program: 60 to 85 °C in 1 min followed by a ramp to 310 °C with 9 °C/min. All other parameters were identical to those used for FAME analysis.

i15:0-PFB oxime was identified by feeding 1 mM  $d_{10}$ -Leucine thrice every 12 h to a culture until an optical density of 1.0-1.3 was reached. The resulting  $d_9$ -i15:0-PFB oxime was detected due to its increase of 9 mass units and slightly lower retention time as discussed by Dickschat *et al.*<sup>84</sup>.

### **Analysis of lysophosphatidylethanolamine**

Fractions containing lysophospholipids were analyzed by means of HPLC ESI-MS. They were dissolved to 10 mg/ml in methanol and 5  $\mu$ l were subjected to a UltiMate 3000 system (Dionex/Thermo Scientific Corp.) coupled to an amaZon X mass spectrometer (Bruker Corp.). Analytes were separated on an Acquity UPLC BEH C18 1.7  $\mu$ m RP column (Waters Corp.) with a length of 50 mm and an inner diameter of 2.1 mm in combination with a MeCN/0.1 % formic acid in water gradient ranging from 5 to 95 % in 22 min at a flow rate of 0.6 mL min<sup>-1</sup>. Lysophosphatidylethanolamines were identified in the positive ion MS<sup>2</sup> mode by a neutral loss of 141  $m/z$  corresponding to the loss of the polar head group. Areas under the curves (AUCs) of the extracted ion chromatograms of each lysophosphatidylethanolamine species were integrated and compared among the respective samples whereas AUCs of the main LPE i15:0-IPE in the vegetative wild type samples was set to 100%.

### **Synthesis of putative acyl acceptors for *in-vitro* acyltransferase assay**

The putative substrates were synthesized similar to a published procedure<sup>85</sup>: About 2 mg of a lipid extracts from the DK1622 *elbD* was dissolved in 1 ml of peroxide free diethylether

by sonication, mixed with 600  $\mu$ l 50 mM tris-malate pH 5.7, 100  $\mu$ l of 100 mM  $\text{CaCl}_2$ , 800  $\mu$ l methanol and 10  $\mu$ l of phospholipase A1 preparation from *Thermomyces lanuginosus* (10 kU/ml; Sigma-Aldrich), vigorously mixed and incubated at 37 °C under agitation for 15 min. Reaction was stopped by the addition of 1.2 ml methanol and 1 ml of dichloromethane (DCM) and lipids were extracted by the method of Bligh and Dyer<sup>34</sup> as described below. Lysophospholipids were dissolved in an aqueous solution of 10 mM dodecylmaltoside (DDM) to a final concentration of about 10 mM. The in this way formed 2-monoacylglycerophosphoethanolamines (2-IPE) as well as 1-monoacylglycerophosphoethanolamines (1-IPE), 2- monoacylglycerophosphates (2-IPA) and 1 - monoacylglycerophosphates (1-IPA) were used as test substrates. 1-IPE was obtained by incubating 2-IPE in 100 mM Tris-HCl for 6 h at 37 °C by acyl migration<sup>86</sup>. 2-monoacylglycerophosphates were generated from 2-IPE by incubation with 2 units phospholipase D from *Streptomyces sp.* Type VII (Sigma-Aldrich) per  $\mu$ mol monoacylglycerolphosphoethanolamine lipid in 50 mM Tris-malate 5 mM  $\text{CaCl}_2$ , 1 mM boric acid and 0.5 % (v/v) n-Butanol for 30 min at 30 °C. 1-IPA was generated from 2-IPA by acyl migration analogously to the formation of 1-IPE.  $d_7$ -i15:0 was used as the acyl donor.

### **Synthesis of putative acyl donors for *in-vitro* acyltransferase assay**

As iso15:0 fatty acid is the predicted and most likely acyl donor for ElbD, we sought to use it in the acyl transferase assay. In order to enhance its detectability using mass spectroscopy, we synthesized the isotope-labeled derivative  $d_7$ -i15:0<sup>87</sup>.  $D_7$ -isopropylmagnesiumbromide (0.227 g, 1.74 mmole, 3 eq.), a small amount of iodine and magnesia shavings (0.085 g, 3.48 mmole, 6 eq.) were mixed under nitrogen and 10 ml of absolute tetrahydrofuran (THF) was added. Grignard-reaction was initiated by short heating. Sodium(12-bromo)dodecanoate (0.175 g, 0.58 mmole, 1eq.) was resuspended in 5 ml THF with dilithiumcopper(I)tetrachloride (0.2 ml, 0.02 mmole, 0.03 eq.) added under agitation to the Grignard preparation. The preparation was stirred overnight and heated the following day for another six hours. After addition of 5 ml 6 M HCl solution and 10 ml water, the preparation was extracted thrice with 15 ml ethylacetate each. Combined organic phases were dried over sodiumsulfate and solvent was removed under removed pressure. The raw product was purified by silica gel column chromatography with a chloroform/methanol gradient (100 % $\rightarrow$ 90 %). 60 mg purified product (41 % yield) was obtained.

This fatty acid was used as free acid and as an *N*-Acetylcysteamine thioester mimicking the activated, ACP-bound fatty acid<sup>88</sup> synthesized as described in the following: 50  $\mu$ mole of  $d_7$ -i15:0 was dissolved in 2 ml of DCM, subjected to  $N_2$  atmosphere in order to ensure water free conditions, cooled to 0 °C, 1 equivalent of 1-hydroxybenzotriazole (HOBt) and 1.1 equivalent of *N*-(3-Dimethylaminopropyl)-*N'*-ethylcarbodiimide hydrochloride (EDC) were added under agitation. Finally, 1.4 equivalents of *N*-acetylcysteamine were added and reaction mixture was incubated for 18 h. Preparation was worked up by addition of 5 ml of DCM and 5 ml of aqueous 1 M HCl, separation of organic phase and aqueous phase was reextracted twice with 10 ml DCM. Combined organic phase was dried over  $Na_2SO_4$ , filtered and evaporated using a rotary evaporator. Formation of,  $d_7$ -i15:0-SNAC was confirmed with NMR. For the acyl transferase assay,  $d_7$ -i15:0-SNAC was dissolved in DMSO to final concentration of 10 mmole/L.

### **Supplementary Note 3: Bioinformatics methods**

#### **General Bioinformatics**

Identification of homologues of proteins or domains mentioned in this study was performed using BLAST-P14<sup>89,90</sup> search within the nr database of NCBI. Prior to design of internal fragments or expression constructs, a frame plot 2.3.2<sup>91</sup> analysis ensured the correct assignment of open reading frames. Sequence alignments were obtained using MUSCLE Alignment<sup>92</sup>. Search for primers suitable for PCR and sequences were constructed using Primer3<sup>93,94</sup>.

The phylogenetic investigations of the ElbD acyltransferase domain were done as follows: Literature was reviewed for reports of acyl acceptor specificity of acyltransferases with known amino acid sequences involved in phospholipid biosynthesis with respect to the constitution of the polar headgroup and the hydroxyl group of the glycerol backbone that is being acylated. The following groups of ATs were included: glycerol-3-phosphate acyltransferases (PlsB/GPAT; EC 2.3.1.15), 1-acylglycerolphosphate acyltransferases (PlsC/AGPAT; EC 2.3.1.51), 2-acylglycerolphosphoethanolamine acyltransferases (Aas/2-LPEAT; EC 2.3.1.40), 1-acylglycerophosphocholine O-acyltransferase (LPCAT; EC 2.3.1.23) as well as all ElbD homologues found in myxobacterial genomes (Supplementary Table 9). For several of these enzymes, multiple substrate recognitions were reported.

Names given to the proteins in a publication were kept. Additional sequences from putative glyceride acylating acyl transferases were obtained by repeated BLAST searches against the nr library of NCBI<sup>95</sup>. Sequence alignments were done using MUSCLE with BLOSUM80 scoring matrix, gap open penalty of 1.53 and an offset value of 0.123. In order to maximize the clustering of the acyltransferase sequences according to their substrate specificity, the alignment was trimmed so that only sequences that align within the AT motifs I-V were taken into consideration resulting in a 325 aa consensus sequence. Sequence alignment was repeated with MUSCLE alignment, this time using BLSOUM30 cost matrix in order to refine the alignment of the now more similar sequences (Supplementary Data Set 3). Based on this trimmed multiple alignment a phylogenetic tree was built using PhyML<sup>96</sup>. Settings were as follows: Substitution model: Dayhoff; branch support: Bootstrap, 500 replicates; proportion of invariable sites fixed to 0; number of substitution rate categories: 4; Optimize: topology/length /rate; topology search: NNI; default, fast (Supplementary Figure 9). Substitution per site were calculated according Dayhoff *et al.*<sup>97</sup>

### ***In-silico* analysis of acyltransferase domains in ElbD**

#### **Homology-modelling of A and AT-domain of ElbD**

The Molecular Operating Environment 2012.10 (MOE) was used to construct homology models of the A- and AT-domain of ElbD<sup>98</sup>. After loading the FASTA sequences into MOE, a BLAST search was performed to find appropriate template crystal structures<sup>89</sup>. Thereafter the primary structures, respectively, of the template and the corresponding target were aligned. To avoid deletions or insertions in conserved regions the alignments were inspected and corrected manually if necessary. Two series each consisting of ten models were constructed with MOE using a Boltzmann-weighted randomized procedure combined with specialized logic for the handling of sequence insertions and deletions<sup>99,100</sup>. The models with the best packing quality functions were selected for full energy minimization using Amber12 and Supporting Hueckel Theory (Amber12EHT). The stereochemical qualities of the models were assessed using Ramachandran plots.

#### **A-Domain:**

For homology modeling the 1.9 Å crystal structure of PheA from *Brevibacillus brevis* (PDBID: 1AMU\_A) was used<sup>101</sup>. The sequence identity of ElbD A-Domain and 1AMU is

~17%. The model used for full energy minimization has a packing score of 2.3. The final model has a root-mean-square deviation (RMSD) of 1.7 Å in relation to the template structure.

#### **AT-Domain:**

For homology modelling the only available 1.5 Å crystal structure of a long chain fatty acid acyl transferase, the Chain A of the glycerol-3-phosphate 1-O-acyltransferase from chloroplasts of *Curcubita moscata* (PDB-ID: 1IUQ\_A) was used as a template<sup>102</sup>. The target and template sequence identity is ~11%. The packing score of the model used for full energy minimization is 2.5. The RMSD between the final model and the template structure is 1.4 Å.

#### **Ligand-Docking**

To predict the binding mode, dockings were carried out by using GOLD version 5.1<sup>103</sup>. The empirical scoring function CEMPLP was used for advanced Protein-Ligand docking<sup>104</sup>. The Binding site of ElbD A-Domain was centered at His253 and for ElbD AT-Domain at His165. The default docking parameters were used.

**Supplementary Data Set 1** | Complete FAME-GC-MS data from Figure 1b in per cent of all fatty acid methyl esters. Values following less-than signs indicate analytes below detection limit. Averages and standard deviations were calculated from three independent biological samples. Colors indicate level of significance (green:  $p < 0.05$ ; yellow:  $p < 0.01$ ; magenta:  $p < 0.001$ ). For details see Supplementary Note 2. DMA: Vinyl ether derived dimethylacetals; OAG: alkyl ether derived *O*-alkylglycerols.

### **6.3.1 Abstract**

Analysis of whole cell lipid extracts of bacteria by means of UPLC MS allows a comprehensive determination of molecular lipid species present in the respective organism and conclusions on both, its metabolic potential as well as the creation of lipid profiles which can visualize the organism's response to the change of internal and external conditions. We describe (i) a fast reversed phase UPLC ESI-MS method suitable for detection and determination of individual lipids from whole cell lipid extracts of all polarities from monoacylglycerophosphoethanolamines to triacylglycerols, (ii) the first overview of a wide range of lipid molecular species in vegetative *M. xanthus* DK1622 cell and (iii) changes of their relative composition in selected mutants impaired in the biosynthesis of alpha-hydroxylated fatty acids, sphingolipids and ether lipids.

### **Supplementary keywords**

lipidomics, myxobacteria, ceramide phosphoinositols, ether lipids, lipid profiles, ESI-MS, reversed phase, UPLC

## 6.3.2 Main text

### Introduction

Myxobacteria are a globally occurring order of soil-dwelling, Gram-negative,  $\delta$ -proteobacteria that attract interest due to a wide range of remarkable features including cooperative motility and predation or simple multicellularity, including fungi-like fruiting body formation (1), and as being producers of a wide range of secondary metabolites (2). Additionally, they proved to exhibit a complex pattern of primary metabolites whereas fatty acyl species and associated lipid belong to the best studied ones. Some of these lipids proved to be involved in processes like chemotaxis or the starvation induced fruiting body formation either as biomarkers or chemotactic signals (3-5). However, to date no methodology is described which enables the investigation of the lipid repertoire of these bacteria as a whole in order to compare changes of the lipid composition on the molecular level in dependency on different metabolic conditions or growth stages.

In the recent years progress was made identifying and elucidating the biosynthesis and putative biological importance of fatty acids (FA) including branched-chain (6), straight-chain (7), unsaturated (8) and hydroxylated FA as well as sphingoid species (9) from myxobacteria particularly with regard to the best studied model organism *M. xanthus*. Analysis focused on fatty acid methyl esters by means of GC-MS or selected lipid classes, so that there is limited information on the complete lipidome of these organisms. High temperature GC-MS was applied on unhydrolyzed lipid extracts (10) in order to elucidate the structure and the relative abundance of neutral lipids and HPLC ESI-MS-MS experiments were used to determine changes in the glycerophosphoethanolamines composition of mutant strains with inactivated acyltransferases (11) on the one hand and to determine the ratio of certain ether glycerophosphoethanolamines to acyl glycerophosphoethanolamines during the process of starvation induced fruiting body formation (4) on the other hand. Results from TLC resolved  $^{32}\text{PO}_4^{3-}$  metabolic labelling studies are available for *Stigmatella aurantiaca* (12), *Myxococcus fulvus* (13) and *Myxococcus xanthus* (14), which give some information about phosphate containing lipid classes and their molar ratio present in those bacteria. However, no comprehensive information of the complete lipidome of myxobacteria are available to date, which is a prerequisite to visualize and evaluate the changes in lipid composition of e.g. mutant strains during vegetative growth or fruiting body formation and can be used as the basis for further investigations for e.g. lipid biomarkers for fruiting body formation.

We sought to find a LC-MS method that (i) is able to resolve as many lipid species as possible ranging from lysophospholipids over glycerophospholipids and glycerolipids; (ii) gives MS and MS/MS spectra from the abundant molecular species in a single run for structure elucidation and identification; (iii) involves the standard setup of UPLC-MS instrumentation used for routine analysis; (iv) solely involves the use of readily available software and (v) needs a very short measuring time.

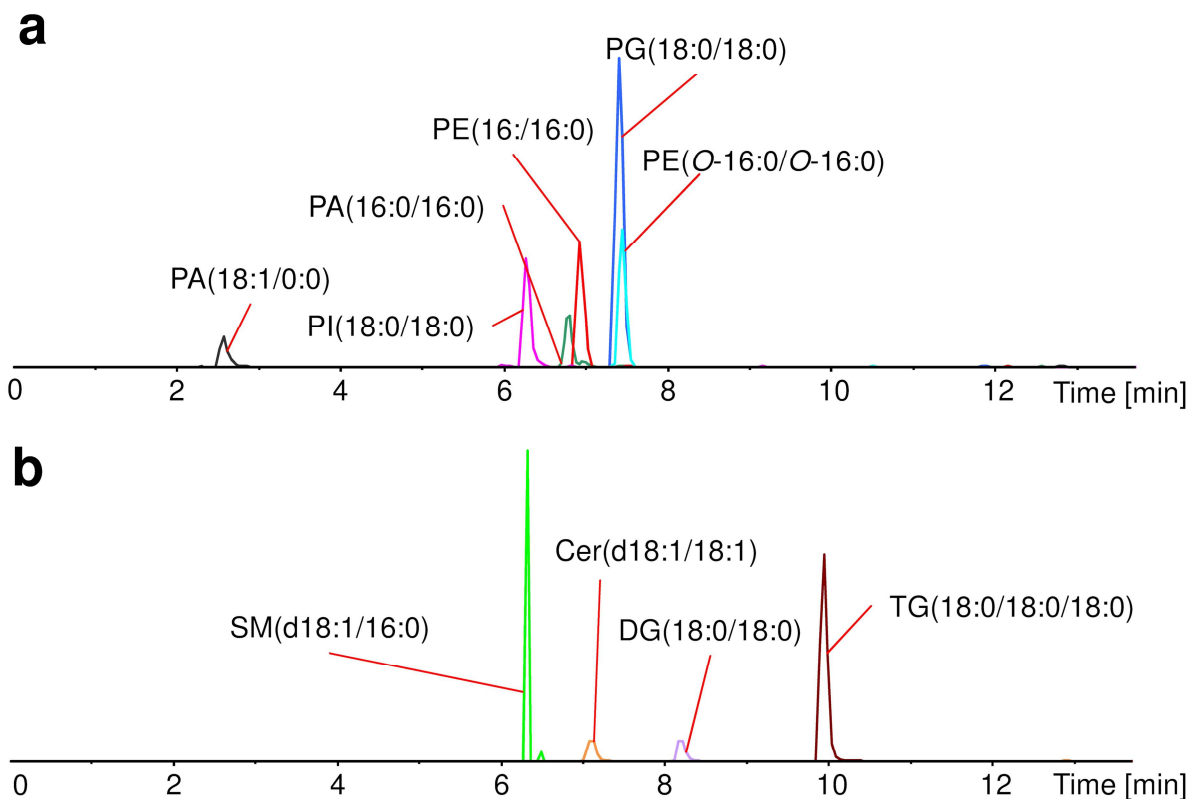

Many lipidomic methods, which involve the direct measurement of lipid species from lipid extracts, base on direct infusion into ESI sources or ionization by MALDI (15, 16) but ion suppression usually impedes the detection of less abundant molecular species in such a complex mixture which can be circumvented by separation of the analytes using a chromatographic technic (17). The development of a comprehensive LC method for lipids proved to be challenging due their highly divers putative physical properties ranging from partly water soluble (lysophospholipids) over amphiphilic (glycerophospholipids) to highly non-polar (glycerolipids), non-ionic (glycerolipids, ceramides) and strongly pH dependent zwitter, cationic and anionic molecules (glycerophospholipids) so that all chromatographic conditions (different eluents, nature and quantity of additives as well as temperature and pH) have to be controlled over the whole chromatographic process. The use of eluent additives is limited as they have to be compatible with MS-coupling.

Many LC methods have been published till now that involve normal phase (NP), hydrophilic/lipophilic interaction chromatography (HILIC), and reversed phase (RP) chromatography in most cases to address particular analytical challenges (18-20). RP-chromatography, which can be regarded as “the” gold standard in routine small molecule analytics, is ideal for resolving molecules even with small differences in polarity so that it became the method of our choice not least being part of the standard instrumentation of our system.

## **Results**

A binary eluent system consisting of water and acetonitrile in solvent A and acetonitrile and isopropanol in solvent B (for details see experimental section) proved to be useful for the separation and elution of a wide range of lipid standards on a RP-18 column (**Figure 1**). The addition of 10 mM ammonium acetate and the adjustment to pH 5.5, which is (i) the buffer optimum of ammonium ions and (ii) an pH at which all major phospholipids have a equable charge state (21, 22), with formic acid in both solvent mixtures gave an

acceptable separation of the lipid extract of *Myxococcus xanthus* DK1622 (23) as depicted in **Figure 2**, whereas ESI-MS/MS allowed the detection and identification of eluting lipid species (**Figure 3-8**).

**Figure 1 | Extracted ion chromatograms of lipid standards from runs using the described LC method.**

a) Data acquired in the negative and b) positive ionization mode with standards mentioned in the materials and method section. All tested lipids could be resolved by the applied eluent system. For details see method section. PA: mono/diacylglycerophosphate; PE(O/O): dialkylglycerophosphoethanolamine; PG: glycerophosphoglycerol; PI: glycerophosphoinositol; Cer: ceramide; SM: ceramide phosphocholine; DG: diacylglycerols; TG: triacylglycerols.

**Figure 2 | Base peak UPLC-ESI-MS chromatograms of a wild type DK1622 lipid extract.**

a) Data acquired in the negative and b) positive ionization mode. PE(P): (plasmeyl)glycerophosphoethanolamines; PG: glycerophosphoglycerols; Cer: Ceramides; PI-Cer: ceramide phosphoinositols; DG: diacylglycerols; TG: triacylglycerols. Most intense signals are discernable in the region of  $R_t = 6.0-8.5$  minutes and  $m/z$  of about 550-850 in the negative ion mode and another large group of signals at  $R_t = 9.0-10.5$  and  $m/z$  of 700-880 in the positive ion mode.

**Figure 3 | Example spectra for glycerophosphoethanolamine (PE) identification.**

Mass spectra of a) PE(16:0/16:0) lipid standard b) PE(15:0/15:0), the main glycerophosphoethanolamine in *M. xanthus*. and c) combined PE(16:2/15:1); PE(15:2/16:1); PE(17:2/14:1) spectrum. Fragment signals derive from  $[\text{RCOO}_{\text{sn-1}}]^-$  /  $[\text{RCOO}_{\text{sn-2}}]^-$  as well as  $[\text{M-H-RCHO}]^-$  and  $[\text{M-H-RCHO-H}_2\text{O}]^-$  (not assigned) ions (25). Carboxylate ions with the higher relative abundance were assigned to the *sn*-2 position of the glycerol backbone (43).

**Figure 4 | Example spectra for glycerophosphoglycerol (PG) identification.**

Mass spectra of a) PG(18:0/18:0) lipid standard b) PG(15:0/15:0), the main glycerophosphoglycerol in *M. xanthus*, and c) combined PG(16:0/16:1); PG(15:1/17:0); PG(15:0/17:1) spectrum. Signals derive from  $[\text{RCOO}_{\text{sn-1}}]^- / [\text{RCOO}_{\text{sn-2}}]^-$  ions as well as  $[\text{M-H}-74-\text{RCH}_2\text{COOH}]^-$ ,  $[\text{M-H-RCHO}]^- / [\text{M-H-RCHO-H}_2\text{O}]^-$  (the latter not assigned) (25). Carboxylate ions with the higher relative abundance were assigned to the *sn*-2 position of the glycerol backbone (43).

**Figure 5 | Example spectra for N-acylsphinganine (Cer) identification.**

Mass spectra of a) Cer(d19:0/17:0) and b) Cer(d19:0/17:0 2-OH). Structure elucidation was performed according to (44). Top spectrum was obtained from  $[M-H]^-$  bottom spectrum from  $[M+HCOO]^-$  molecular ion. Molecular composition was confirmed using hrMS (see **Table 3**).

**Figure 6 | Example spectra for ceramide phosphoinositol (PI-Cer) identification.**

MS<sup>2</sup> fragment spectra of a) PI-Cer(d19:0/17:0) and b) PI-Cer(d19:0/17:0 2-OH). Fragments are [IP]<sup>-</sup>, [IP-H<sub>2</sub>O]<sup>-</sup>, [P-Cer-H<sub>2</sub>O]<sup>-</sup> and [P-Cer]<sup>-</sup> (41, 42). Molecular composition was confirmed by hrMS (see **Table 3**).

**Figure 7 | Example spectra for diacylglycerol (DG) identification.**

MS<sup>2</sup> fragment spectra of a) DG(18:0/18:0) standard b) DG(15:0/15:0) and c) DG(33:0) from [M+NH<sub>4</sub>]<sup>+</sup> molecular ion. Fragment ions derive from neutral loss of fatty acid derived keten moieties and water [M-NH<sub>3</sub>-H<sub>2</sub>O-RCHCO]<sup>+</sup> (24).

**Figure 8 | Example spectra for triacylglycerol (TG) identification.**

MS<sup>2</sup> fragment spectra of a) TG(18:0/18:0/18:0) standard b) TG(15:0/15:0/15:0) and c) TG(48:3) from [M+NH<sub>4</sub>]<sup>+</sup> molecular ion. Fragment ions derive from neutral loss of fatty acids and ammonia ([M-NH<sub>3</sub>-R<sub>n</sub>COOH]<sup>+</sup>) (corresponding to fatty acids C14:1 to C18:2) and fatty acid derived [R<sub>n</sub>CO + 74]<sup>+</sup> ions (24). Exact assignment of fatty acyl residues to glycerol backbone was not possible under these conditions.

## Lipid profile of *Myxococcus xanthus*

Applying the described method on normalized lipid extracts resulted in two sets of LC-MS data for each sample: one recorded in the positive ion mode the other one in the negative ion mode. **Figure 2** shows the resulting base peak chromatograms (BPC) of the UPLC-MS runs of lipid extracts from vegetatively grown DK1622 wild type cells recorded in the negative (**Figure 1 a**) and the positive (**Figure 1 b**) ion mode respectively.

Evaluation of the autoMS<sup>2</sup> Data of these signals resulted in the identification of a large number of PE and PG species as well as the previously identified 1-(1Z-alkenyl),2-acylglycerophosphoethanolamines (PE(P)) (4) (**Figures 3-4**). Hydroxylated and non-hydroxylated N-acylsphinganine (Cer) (**Figures 5**) and interestingly, for the first time in myxobacteria, ceramide phosphoinositols (PI-Cer) (**Figures 6**; for a summary see **Supplemental Table 1 and 2** the full data set obtained from Data Analysis) are detectable as less abundant compounds, which is consistent with the relative small abundance and limited diversity of sphingoid bases determined by GC-MS analysis of lipid methanolysed cell extracts (**Table 1**).

Fragmentation spectra of the late eluting molecules in the positive ionization mode are consistent with ammonium adducts of diacylglycerols (DG) and triacylglycerols (TG) (24) (**Figure 7-8**) as well as protonated ceramides. PEs are the only detectable glycerophospholipids species as distinguishable by the  $[M-141+H]^+$  MS<sup>2</sup> fragment resulting from the neutral loss of the polar headgroup. They were not further evaluated as these fragment spectra do not contain additional information.

None of the evaluated MS<sup>2</sup> spectra gave evidence for other glycerophospholipids, glycerolipids or precursors of identified lipids like, lysophospholipids, diacylglycerophosphoserines or CDP-diacylglycerols.

Concerning the elution pattern of these lipid species, under our conditions the following regularities can be observed (**Figure 2, Supplemental Table 1 and 2**):

1. As expected, with increasing length of the acyl chains attached to the glycerophospholipids, retention time increases as non-polar interaction with the RP-18 stationary phase increase.

2. Elution order for glycerophospholipids is PGs → PEs → pPEs when the number of carbon atoms and the degree of saturation in the acyl side chains are identical.
3. PI-Cers elute earlier than Cers whereas  $\alpha$ -hydroxylation in the acyl side chain further decreases the retention time.
4. For DGs and TGs, analogously to the glycerophospholipids, retention time increases with acyl chain length and degree of saturation.
5. Lipids from the same class with an identical overall carbon and double bond number generally co-elute. Still, data from MS<sup>2</sup> fragmentation of glycerophospholipids in the negative ion mode allows the assignment of fatty acyl residues to *sn*-1 or *sn*-2 positions of the glycerol backbone of those lipid species **(Figure 3-4)**.

In total 3 ceramide, 4 ceramide phosphoinositols, 52 glycerophosphoethanolamines, two 1-(1Z-alkenyl),2-acylglycerophosphoethanolamines, 20 glycerophosphoglycerols, 7 diacylglycerols could be identified. 46 triacylglycerol molecular species were identified as well. The exact assignment of all three fatty acyl moieties to the three hydroxyl functions of the glycerol backbone was not possible. Fragment spectra of triacylglycerols indicated a high variance of those molecules with almost all saturated and unsaturated fatty acyls present in *M. xanthus* so that each molecular ion consists of several isobaric triacylglycerol species. **(Figure 8c)**.

UPLC-MS analysis allows the assignment of a particular polar headgroup to ceramides and detects loss of lipid species

We applied the method and data evaluation procedure on lipid extracts of vegetatively grown cells from various strains with mutations in various genes involved in lipid biosynthesis. Strain  $\Delta$ 0191 lacks a fatty acid hydroxylase, which is responsible for the formation of 2-OH fatty acids (**Table 1**). Strain  $\bar{M}$ XAN\_3748 bears a mutation in a serine-palmitoyl-CoA acyltransferase homologue and is known to be incapable of sphingoid base formation (9) (**Table 1**). **Figure 9 a-c** shows EICs of various ceramide

species from wt,  $\Delta 0191$  and  $\bar{M}XAN_{3748}$  extracts.  $\Delta 0191$  shows the selective loss of hydroxylated ceramides,  $\bar{M}XAN_{3748}$  does form neither Cers nor PI-Cers anymore as determined by both low resolution MS and confirmative high resolution MS experiments (**Table 3**).

Analogously, in strain  $\bar{M}XAN_{1528}$ , that bears a mutation in *elbD*, a multidomain enzyme involved in ether lipid biosynthesis (4), the relative abundance of vinyl ether species is strongly reduced (**Supplemental Table 2, Figure 9 d**).

#### Lipid profiles of various mutants deficient in lipid biosynthesis

Integration of the EIC peak areas of the monoisotopic masses of the respective lipid molecular species allows the construction of lipid profiles. If only the relative proportion of all lipid species are being compared among the various strains investigated, no major differences are observable apart from the afore mentioned loss of certain lipid species and the expected relative increase of the remaining molecular species (**Figure 10**).

**Figure 9 | Extracted Ion chromatograms of identified N-acylsphinganes and ceramide phosphoinositols.**

Chromatograms are from *M. xanthus* a) wild type b)  $\Delta 191$  c)  $\Delta$ MXAN\_3748. Intensity scale is normalized to  $10^8$  counts. Red lines: hydroxylated ceramide phosphoinositols; blue: non-hydroxylated ceramide phosphoinositols; orange: hydroxylated N-acylsphinganes; green: non-hydroxylated N-acylsphinganes. Asterisks indicate signals due to overlapping isotopic peaks from other molecular species unrelated to sphingolipids. d) Superimposed chromatograms of PE(15:0/15:0) (red), PE(P-15:0/15:0) (blue) of wild type (solid) and  $\Delta$ MXAN\_1528 (dashed) reflecting the reduction of vinyl ether production as also visible in **Table 1**.

**Figure 10 | Ratio of lipid species present in lipid extracts.**

Ratios of lipid species present in various strains of *M. xanthus* given in per mil of total lipid AUC determined for the DG and TG in the positive and all other lipid species in the negative ionisation mode. TG: triacylglycerols; DG: diacylglycerols; PG: glycerophosphoglycerols; PE(P): 1-(1Z-alkenyl)-2-acylglycerophosphoethanolamines; PE: glycerophosphoethanolamines; PI-Cer: ceramide phosphoinositols; Cer: N-acylsphinganine.

To get further insights into the lipid profile of *M. xanthus* we constructed a scatter plot comprising mass, retention time and relative abundances of all analyzed lipid molecular species given as per mil of the sum of all peak areas (**Figure 11**). The observed pattern reflects previous results from GC-MS analysis of fatty acid methyl esters and neutral lipids with a high proportion of lipid molecular species containing 15:0 and 16:1 (**Table 1** and **2**). It seems that the occurring fatty acids are somewhat equally distributed among the various lipid classes with almost “Gaussian” like distribution among the triacylglycerols. Like *Curtis et al.*(11) we identified many PE and also PG molecular species with unsaturated fatty acids attached to the *sn*-1 position of the glycerol backbone, indicating a less specific glycerol-3-phosphate 1-*O*-acyltransferases activity compared to e.g. *E. coli* where those lipids are less prevalent (25). Vinyl ether containing phospholipids were exclusively detected within the glycerophosphoethanolamine molecules with a high overall proportion

whereas *O*-alkylglycerols could not be detected under these conditions, which is consistent with previous results (4).

**Figure 11 | Lipid profile of *M. xanthus* DK1622 wild type.**

Data from Table 2 visualized in a scatter plot with relative abundance of individual lipid molecular species given as per mil of the total abundance of all lipid species separately determined for the positive and negative ionization mode. PE(P): (plasmeyl)glycerophosphoethanolamines; PG: glycerophosphoglycerols; Cer: Ceramides; PI-Cer: ceramide phosphoinositols; DG: diacylglycerols; TG: triacylglycerols.

In an additional step, we created scatter plots, comparing the relative changes in the abundance of the individual lipid species of the mutant lipid profiles compared to the wild types profiles. This reflects the changes in the abundance of individual molecular species in the analyzed mutant strains compared to the wild type, displayed as a whole in a three-dimensional way in order to visualize changes in their profile (**Figure 12 a-c**).

The fairly low proportion of glycerophosphoglycerols is consistent with results from *Orndorff et al.* (14) who specified the amount of glycerophosphoglycerols 9 % of total  $^{32}\text{PO}_4^{3-}$  labelled *M. xanthus* membranes. Neutral lipids, especially triacylglycerols gave strong signals as ammonium adducts although they are less prevalent in vegetative cells (10). Their molecular diversity seems to be even higher than that of the polar lipids.

Lipid profile of strain  $\Delta 0191$  vs. wild type shows that, apart from the afore mentioned loss of hydroxylated ceramide molecular species and the expected relative increase of non-hydroxylated ceramides (**Figure 12, Table 2**), there is a general increase in the abundance of PG molecular species and (**Figure 12 a**). Within the PE species, there is a conspicuous increase in PE(15:0/17:0) with PE(15:0/15:0) and PE(15:1/15:0) strongest decreased in abundance. This matches well with the FAME pattern of strain  $\Delta 0191$ , which shows a

higher proportion of i17:0 fatty acid than the wild type. The changes in abundance within the triacylglycerol molecular species seem to be rather random however might also be attributed to more i17:0 and less i15:0.

**Figure 12 b** visualizes the changes in the lipid profile of  $\Delta$ MXAN\_3748 compared to the wild type. A general increase in higher molecular weight lipid species within the PE, PG, TG molecular species as well as a greater proportion of PE(P) can be observed which means that there is a general increase in longer and/or less saturated fatty acids that could compensate for the loss of the lipophilic ceramide species.

The scatter plot in **Figure 12 c** shows the expected decrease of PE(P-15:0/15:0) in the  $\Delta$ MXAN\_1528 mutant. Rather surprising is the synchronous relative drop in PE(15:0/15:0) and TG(15:0/15:0/15:0) suggesting a common precursor of all these lipid species.

## Discussion

Such comprehensive data sets about molecular lipid species in myxobacteria has not been published before. *Curtis et al.* (26) reported the analysis of lipid molecular species from the PE fraction of *M. xanthus* by HPLC ESI-MS resulting in the identification of 26 PE molecular species whereas for four of them no assignment of the fatty acyl residues to the *sn*-1 and *sn*-2 position of the glycerol backbone was achieved.

**Figure 12 | Relative changes in the lipid profile of  $\Delta 0191$  (a),  $\overline{\text{MXAN}}_{3748}$  (b) and  $\overline{\text{MXAN}}_{1528}$  (c) vs. wild type.**

For details see text and Supplemental **Table 1**. PE(P): (plasmeyl)glycerophosphoethanolamines; PG: glycerophosphoglycerols; Cer: Ceramides; PI-Cer: ceramide phosphoinositols; DG: diacylglycerols; TG: triacylglycerols.

Our UPLC-MS analysis confirmed that  $\alpha$ -hydroxylation of fatty acids and sphingolipids are indeed metabolically linked in such a way that the lipid extract of the  $\alpha$ -hydroxylase deletion mutant  $\Delta 0191$  lacks the hydroxylated sphingolipids and the *spt*-disruption mutant  $\overline{\text{MXAN}}_{3748}$  is devoid of any detectable sphingolipids with nor further molecules bearing a  $\alpha$ -hydroxylated fatty acid. When the results concerning the abundance of neutral

lipids are compared to those obtained by high temperature GC-MS analysis (10) it seems that the latter method overestimates the presences of mono- and diacylglycerols very likely due to the derivatisation with MSTFA, which converts them in easily ionizable molecules. We conclude from this observation that the neutral lipid pattern by ESI-MS is more representative than the data obtained by high temperature GC-MS. Interestingly, though not further evaluated, triacylglycerol molecular species seem to contain also fatty acyl species that are not detectable in FAME-GC-MS analysis as e.g. the  $[M-NH_3-R_nCOOH]^+$  fragment at  $m/z$  521.6 in the mass spectrum shown in **Figure 8 c** indicates neutral loss of a 18:1 fatty acid.

The presence of ceramide phosphoinositol is an interesting finding of this study as this is a lipid known to be present in fungi like *Saccharomyces cerevisiae* (27) and *Aspergillus niger* (28) but were also found in protozoan pathogens like *Trichomonas brucei* (29) and plants (30), however to our knowledge not described before in bacteria. In general, ceramides seem to be rather common as they were found in all myxobacteria investigated for this lipid class with ceramides detected in *Cystobacter fuscus* (31), ceramide phosphoethanolamines in *Myxococcus stipitatus* (32), ceramide phosphoethanolamines,  $\beta$ -D-Glucosylsphingenines and even phosphosphingolipids in *Sorangium cellulosum* So ce56 (33), where they serve together with ornithine containing lipids and glycerol etherlipids as substitutes for missing lipopolysaccharides in the outer membrane (33).

In *Saccharomyces cerevisiae* ceramide phosphoinositols are synthesized by the inositol phosphorylceramide synthase catalytic subunit (AUR1), an enzyme that transfers a phosphoinositol headgroup to  $\alpha$ -hydroxyceramides from diacylglycerophosphoinositol moiety(34). Protein MXAN\_0451 (annotated as PAP2 family protein) is 29% homologous to AUR1 (E-Value =  $2^{-20}$ ) a further indication for *M. xanthus* capability to synthesize this lipid species. Interestingly no diacylphosphoinositols were detected in the lipid extracts though it was noted before that a *myo*-inositol-1-phosphate synthase homologue (MXAN\_0452) as well as a CDP-alcohol phosphatidyltransferase homologue (MXAN\_0450) are encoded next to MXAN\_0451 (35). This may be due to a fast conversion of diacylglycerophosphoinositols to ceramide phosphoinositols as the occurrence of diacylglycerophosphoinositols are indeed described for *M. fulvus* and *Stigmatella aurantiaca* (12).

Glycosylated ceramides in general are important signaling molecules in multicellular organisms (36) but no specific function for PI-Cers are known in lower eukaryotes except that inhibition of AUR1 is lethal to *Saccharomyces cerevisiae* (37) and that PI-Cer is at least indirectly associated with pathogenicity of *Cryptococcus neoformans* (38). A possible signaling function in e.g. fruiting body formation or sporulation of PI-Cers and ceramides in general in *M. xanthus* remains to be investigated. Although no systematic investigations on putative signaling functions of ceramides are available in bacteria it was noted that sphingolipids (as determined by the hydrolysis derived sphingobases) accumulate in developing *M. xanthus* cells but are dispensable for fruiting body formation (9).

We are aware that final statements concerning the changes of the lipid profiles are not possible without statistically analyzable data but some observable changes, like the previously established decrease or loss of selected molecular species and the easily explainable general increase in degree of saturation and chain length of fatty acids within the lipids suggest that this is generally a valid approach whereat the visualization of the data using scatter plots resolved by the lipid class strongly facilitates data inspection and interpretation. This facet will become even more important the higher the number of analytes becomes. We envision that after refinement of this method utilizing appropriate internal standards and statistics the obtained lipid profiles can be linked to other properties like transition profiles or diffusibility of membranes, activities of selected membrane proteins and membrane proteomes in order to unravel the multifactorial links between those properties

### 6.3.4 Experimental section

#### Materials, chemicals and analytical standards

Water (H<sub>2</sub>O), methanol (MeOH), acetonitrile (ACN) and dichloromethane (DCM) (all Carl Roth) used as solvents and eluents were of LC-MS grade. HPLC grade ammonia (Sigma) was used as a 10% aqueous solution and formic and acetic acid (both Carl Roth) were of analytical grade. Glyceryl tristearate ~99% (TG(18:0/18:0/18:0); [M+NH<sub>4</sub>]<sup>+</sup> = 908), rac-1,2-distearoylglycerol ~99% (GC) (DG(18:0/18:0/0:0); [M+NH<sub>4</sub>]<sup>+</sup> = 642), 1,2-dipalmitoyl-*sn*-glycero-3-phosphoethanolamine, syn. >97% (PE(16:0/16:0); [M-H]<sup>-</sup> = 690), 1,2-distearoyl-*sn*-glycero-3-phospho-*rac*-(1-glycerol) sodium salt (PG(18:0/18:0); [M-H]<sup>-</sup> = 777), 1,2-dihexadecyl-*sn*-glycero-3-phosphoethanolamine ≥ 99.0% (TLC) (PE(*O*-16:0/*O*-16:0); [M-H]<sup>-</sup> = 663), 1,2-dipalmitoyl-*sn*-glycero-3-phosphate sodium salt ≥99% (Sigma) ((PA(16:0/16:0); [M-H]<sup>-</sup> = 648), oleoyl-L- $\alpha$ -lysophosphatidic acid (PA(18:1/0:0); [M-H]<sup>-</sup> = 436), ceramide from bovine brain >98% (TLC) (mainly Cer(d18:1/18:1)), L- $\alpha$ -phosphatidylinositol from *Glycine max* (mainly PI(18:0/18:0); [M-H]<sup>-</sup> = 833), sphingomyelin from chicken egg yolk, ~99% (mainly SM(d18:1/16:0); [M+H]<sup>+</sup> = 703) were obtained from Sigma as analytical standards for the development of the optimal eluent system and to produce reference spectra. Stock solutions with a concentration of 1 mg/ml were prepared of each standard in either DCM:MeOH:H<sub>2</sub>O 65:35:8 (V/V/V) for the ceramides and phospholipids and ACN:DCM 1:1 (V/V) for the neutral lipids and diluted to a final concentration of 50  $\mu$ M in MeOH:DCM:H<sub>2</sub>O 70:35:5 (V/V/V) prior to HPLC-MS analysis.

#### Strains and growth conditions

*Myxococcus xanthus* DK1622 wild type and mutant strains were grown in 150 ml CTT media (10 g Casitone (Difco), 8 mM MgSO<sub>4</sub>, 1mM K<sub>2</sub>HPO<sub>4</sub>, 10 mM Tris-HCl, pH 7.6) supplemented with 40  $\mu$ g/ml Kanamycin when appropriate at 30 °C and 230 rpm on a rotary shaker in 1l conical flasks to an optical density of OD<sub>600</sub> ~1.6. Strains  $\Delta$ 0191 and <sup>-</sup>MXAN\_3748 are published elsewhere (9). Strain <sup>-</sup>MXAN\_1528 bears a mutation in *elbD*, a multidomain enzyme involved in ether lipid biosynthesis (4).

#### Extraction procedures

Cells were harvested by centrifugation at 15,000 x g for 15 minutes at room temperature and washed ones with the same amount of distilled water.

A modified method of Bligh and Dyer (39) was applied to extract all lipids. The cell pellets were thoroughly resuspended in 2 ml of distilled water and 7.5 ml of a mixture of MeOH/DCM 2:1 (V/V) was added. After incubation for 20 minutes under agitation, phase separation was induced by the addition of 2.5 ml of DCM and water respectively. The lower phase was removed after centrifugation at 750 x g for 20 minutes and the cells and upper phase was reextracted twice with 2 ml DCM. The combined lower phases were filtered through solvent resistant 0.22  $\mu$ M PTFE membrane filters and dried under a stream of nitrogen at 40 °C in weighted vials for exact determination of the extracts mass. For analysis the lipid extracts were dissolved in mixture of MeOH:DCM:H<sub>2</sub>O (70:35:5 V/V/V) to a final concentration of 10 mg/ml.

#### GC-MS fatty acid methyl ester (FAME) analysis

Derivatization procedures and GC-MS conditions are described somewhere else (40).

#### HPLC-MS Conditions

For every data set 5  $\mu$ l of lipid extract was separated on a ACQUITY UPLC™ BEH C18 column (Waters) with a length of 50 mm an inner diameter of 2.1 mm and a mean particle size of 1.7  $\mu$ M connected to a UltiMate 3000 (Thermo) HPLC system coupled to an amaZonX (Bruker) mass spectrometer at a constant flow rate of 0.6 ml/min a temperature of 50 °C and a binary gradient. Eluent A consisted of water/acetonitrile 50/50 (V/V) and solvent system B of acetonitrile/isopropanol 10/90 (V/V). Both eluents contained 10 mM NH<sub>4</sub>AcO as a buffering additive and were set to a pH of 5.5 using formic acid in order to maintain the analytes in the same charge state during the separation process. The gradient was programmed as follows: Start at 1% B, increased to 95% within 10 minutes in a linear manner, hold at 95% for 2 minutes and reequilibration was performed for 2 minutes at 1% B.

The ESI parameters were: capillary voltage: +4.5 kV (negative mode); -4.5kV (positive mode); end plate offset: -500.0 V; capillary exit: -140.0 V (negative mode) +140.0 V (positive mode); nitrogen flow: 11.83 l/min; drying gas temperature: 300 °C; nebulizing gas pressure: 44.00 psi.

Both, UPLC-MS and UPLC-MS/MS were recorded in the same run using the “ultra” scan mode with a trap drive of 64.3 (negative mode) and 53.3 (positive mode) respectively, a scan speed of 25,000  $m/z$  per second and the mass resolution was 0.6  $m/z$  over a range of

100-1000  $m/z$  whereas one spectrum was an average of 7 scans in the MS mode and 3 scans in the MS<sup>2</sup> mode. For autoMS/MS fragmentation an absolute threshold of 25000 cts was chosen and already fragmented precursor ions were excluded for further fragmentation after two spectra for 0.5 minutes. The isolation width was 1.5  $m/z$ .

### Data Processing

For the visualization, processing and analysis of the HPLC-MS data the programs DataAnalysis Version 4.0 SP 2 (Build 274, Bruker) was used in combination with LibraryEditor Version 4.0 SP 2 (Build 274, Bruker) and Excel 2010 (Version 14.0.7106.5003 (32-Bit)).

In a first step a LibraryEditor library was established to enable automatic identification of lipid species from the lipid extracts. MS<sup>2</sup> spectra that were acquired during the runs automatically were extracted from the dataset using the “Compound-autoMS(n)” algorithm with the following settings: intensity threshold positive: 1,000,000; intensity threshold negative 10,000; Maximum number of compounds: 350; retention time window (min): 0.25; spectrum type: line spectra only; background subtraction: none. Lipid species were identified from the MS<sup>2</sup> spectra and added to the library together with their retention times. This library was applied to all HPLC-MS runs using the “Identify Mass Spectra” function of Data Analysis with the following settings: Desired score: 900; Minimum score: 600; minimum parameter matching score: 250; maximum number of spectra: 1; accepted retention time deviation: 0.1 minutes; maximum retention time deviation: 0.2 minutes.

For the calculation of the relative % of lipid species Extracted Ion Chromatograms (EICs) were created for every single precursor ion of the identified lipid species. For better peak detection all chromatographic traces were smoothed using a Gaussian algorithm (1 pt width, 2 cycles). Those EICs from the identified lipid species were integrated by applying the “Compounds-Chromatograms” algorithm with the following settings: S/N threshold: 5; Area threshold: 10%; Intensity threshold: 10000 for the negative ion mode and 1000000 for the positive ion mode; skim ratio: 0; smoothing width: 1. Charts containing the identified autoMSn compounds and the AUCs of the EICs were exported into Excel charts. Those charts were manually inspected for false identifications and missing EIC peak integrations.

Peak areas of PEs, PGs, PI-Cers, the formate adducts of Cers and pPEs from the HPLC-MS runs in the negative ion mode and the DGs and TGs in the positive ion mode were separately summed up and normalized to 1000, and the peak area of each individual EIC peak was calculated as per mil of the total integral of all peak (see **Supplemental Table 2** and **3** for the complete data set and **Table 2** for a summary).

For the visualization of the base peak full scan UPLC-ESI-MS chromatograms and plotting the lipid profiles MATLAB Release 2013b (**The MathWorks, Inc., Natick, Massachusetts, United States**) was used. The base peak full scan UPLC-ESI-MS chromatograms were created by using the functions “meshgrid” and “surf”. The “stem3” function was applied to create the 3D lipid profiles.

### Identification of lipids by MS

The experiments of the positive ionization and the negative ionization mode were combined in order to identify a maximal possible number of lipids. The above mentioned standards were used in order to evaluate the chromatographic and fragmentation behavior of those lipid species. Those information plus the reference spectra and software tools from [www.lipidmaps.org](http://www.lipidmaps.org) were used as the bases for the MS based structure elucidation of the lipid species. The fragmentation behavior of ceramide phosphoinositols (PI-Cers) have been described previously (41, 42). HPLC-ESI-MS data for the identification of structure elucidation of glycerophosphoglycerols (PGs), glycerophosphoethanolamines (PEs) are already available as well (25, 43). The presence of PGs, PEs, N-acylsphingamines (Cers) as well as the presence of distinctive  $\alpha$ -hydroxylated fatty acids together with the complete fatty acid profiles of the investigated strains have been published (9, 11, 13, 14).

In the negative ion mode, PGs and PEs were detected as  $[M-H]^-$  ions and Cers, both hydroxylated and non-hydroxylated, as  $[M+HCOO]^-$  ions respectively.

PEs, Cers (dihydroceramides), diacylglycerols (DAGs) and triacylglycerols (TAGs) were detected in the positive ion mode, the former two as  $[M+H]^+$  ions and the latter two as  $[M+NH_4]^+$  Ions.

In general, isobaric molecular species could not be resolved by HPLC so that they yielded one MS<sup>2</sup> spectra (see **Supplemental Table 2** and **3, Figure 3-8**)

For the creation of the lipid profiles only the integrals from the negative ion mode for the PEs, PGs, PI-Cers and Cers and from the positive ion mode for the DGs and TGs were used. PE and Cer ions were also clearly detectable in the positive ion mode but not used for the creation of lipid profiles.

#### High resolution MS readings

Determination of the exact mass of ceramide molecular species from lipid extracts was carried out using a Dionex Ultimate 3000 RSLC coupled to a Bruker micrOTOF-Q II equipped with an electrospray ionization source set to negative ionization mode. HPLC settings were identical to those described above though the column bed was 100 mm in length and the gradient length was doubled to 20 min accordingly. The mass spectrometer was calibrated using a sodium formate calibrant solution (10 mM). MS data were acquired within the mass range of 200-2000  $m/z$ .

#### Nomenclature

For the sake of uniformity and comprehensibility we used the nomenclature of the LIPID MAPS Lipid Classification System (see [www.lipidmaps.org/data/classification/LM\\_classification\\_exp.php](http://www.lipidmaps.org/data/classification/LM_classification_exp.php)) for the names and abbreviations.

### 6.3.5 Supplemental data

**Supplemental Table 1** | Identified molecular species with relative AUCs given as per mil of the total AUC of all identified lipid molecular species determined separately for the positive and negative ionization mode. “Difference” is relative AUC differences in per mil between the mutant and wild type strain and basis for the plots in **Figure 12**. Lib. MW is calculated molecular weight of monoisotopic mass of respective lipid species. Retention times are those determined by the softwares peak detection algorithm. Abs.: absolute; Rel.: relative.

**Supplemental Table 2** | Complete table of lipid species identified by the procedure described in the method section. Lipid species highlighted in red were not fragmented in the respective run, but the peaks were detected at the given retention time in the extracted ion chromatogram.

## 7 Curriculum vitae

### Personal information

Date of birth: 31.10.1981  
Birthplace: Berlin  
Nationality: German

### Professional experience

04/2009 – 03/2014 Scientific assistant and doctoral candidate / Merck-Endowed Professorship Molecular Biotechnology (Prof. Dr. Helge B. Bode) / Goethe University Frankfurt (Germany)  
03/2008 – 03/2009 Scientific assistant and doctoral candidate / Emmy-Noether junior research group (Dr. Helge B. Bode) / Department of Pharmaceutical Biotechnology Saarland University (Saarbrücken, Germany)  
11/2007 – 01/2008 Pharmacist / Syringen Pharmacy (Berlin, Germany)

### Academic and college education

02/2007 – 08/2007 Postgraduate student / School of Pharmacy (Prof. Dr. Thomas Rades) / University of Otago (Dunedin / New Zealand); title PGCert report: “Influence of Various Excipients on the Dehydration of Carbamazepine Dihydrate in a Solid Dispersion”  
Postgraduate Certificate in Pharmacy  
01/2007 Completion of the third part of the pharmaceutical examination  
License to work as a pharmacist  
Diploma in pharmaceutical sciences  
07/2006 – 12/2006 Internship for pharmacists, second part and diploma student / ProBioGen AG (Berlin, Germany) and Ernst-Moritz-Arndt University (Greifswald, Germany) Supervisors: Prof. Dr. Ulrike Lindequist and Dr. Stefan Zietze; title diploma thesis: “Der Einfluss verschiedener Hilfsstoffkombinationen auf die Stabilität von rekombinant hergestelltem  $\alpha_1$ -Antitrypsin”

01/2006 – 06/2006	Internship for pharmacists, first part / Gorki Pharmacy (owner: Dr. Sabine Knoll) (Berlin-Tegel, Germany)
10/2001 – 12/2005	Pharmaceutical studies / Free University Berlin (Germany), second part of the pharmaceutical examination
06/2001	General qualification for university entrance
01/1999 – 06/1999	Guest student Morrinsville College (Morrinsville, New Zealand)
08/1994 – 06/2001	Lutheran School Frohnau (grammar school) (Berlin, Germany)
08/1988 – 07/1994	Primary School “Am Fließtal” (Berlin, Germany)

### **Further professional engagements:**

2008 / 2010	Replacement services pharmacy / Charlotten Pharmacy (Berlin-Spandau, Germany)
2011 – 2012	Replacement services pharmacy / Delphin Pharmacy (Frankfurt/Main, Germany)
	Member / German Pharmaceutical Society (DPhG e.V.)
	Training certificate Regional Chamber of Pharmacists for Hessen
	Certificate of the Goethe Graduate Academy (GRADE)

## 8 Publications

**Lorenzen, W.**, Ahrendt, T., Bozhüyük, K. A. J., Bode, H. B. (2014) A multifunctional enzyme is involved in a novel bacterial ether lipid biosynthesis pathway. *Nature Chemical Biology*

DOI: 10.1038/NCHEMBIO:1526

Brat, D., Weber, C., **Lorenzen, W.**, Bode, H. B., and Boles, E. (2012) Cytosolic re-localization and optimization of valine synthesis and catabolism enables increased isobutanol production with the yeast *Saccharomyces cerevisiae*. *Biotechnology for biofuels* 5, 65.

DOI:10.1186/1754-6834-5-65

Brachmann, A. O., Reimer, D., **Lorenzen, W.**, Alonso, E. A., Kopp, Y., Piel, J., and Bode, H. B. (2012) Reciprocal cross talk between fatty acid and antibiotic biosynthesis in a nematode symbiont. *Angewandte Chemie (International ed. in English)* 51, 12086-9.

DOI: 10.1002/anie.201205384

Bode, H. B., Reimer, D., Fuchs, S. W., Kirchner, F., Dauth, C., Kegler, C., **Lorenzen, W.**, Brachmann, A. O., and Grün, P. (2012) Determination of the absolute configuration of peptide natural products by using stable isotope labeling and mass spectrometry. *Chemistry (Weinheim an der Bergstrasse, Germany)* 18, 2342-8

DOI: 10.1002/chem.201103479

**Lorenzen, W.**, Ring, M. W., Schwär, G., and Bode, H. B. (2009) Isoprenoids Are Essential for Fruiting Body Formation in *Myxococcus xanthus*. *Journal of Bacteriology* 191, 5849-53.

DOI: 10.1128/JB.00539-09

Ohlendorf, B., **Lorenzen, W.**, Kehraus, S., Krick, A., Bode, H. B., and König, G. M. (2009) Myxotyrosides A and B, Unusual rhamnosides from *Myxococcus sp.* *Journal of Natural Products* 72, 82-6.

DOI: 10.1021/np8005875

**Lorenzen, W.**, Bozhüyük K. A. J., Cortina, N. S., Bode, H. B. (2014) A comprehensive insight into the lipid composition of *Myxococcus xanthus* by UPLC ESI-MS *The Journal of Lipid Research* (currently in revision)

## 9 Record of conferences

### **Joint Meeting of the Austrian and German Pharmaceutical Societies 2011 „Shaping the future – Trends and Perspectives in Pharmaceutical Sciences“**

20.9.-23.9.2011

Innsbruck, Austria

Contribution: poster

### **DPhG Annual Meeting 2010 “Personalisierte Therapeutika – Traum oder Wirklichkeit? (Personalised Therapy – Dream or Reality?)”**

4.10.-7.10.2010

Brunswick, Germany

Contribution: None

### **37th International Conference on the Biology of Myxobacteria 2010**

29.8.-01.09.2010

Nonnweiler-Otzenhausen/Saarland, Germany

Contribution: poster + oral poster presentation

### **3rd European Conference on Chemistry for Life Sciences**

2.9.-5.9.2009

Frankfurt/Main, Germany

Contribution: poster + oral poster presentation

### **DPhG Annual Meeting 2009 „Biotechnologisch erzeugte Wirkstoffe: Konzepte, Erfolge, Erwartungen (Bioengineered Active Ingredients: Concepts, Achievements, Expectations)“**

28.9.-1.10.2009

Jena, Germany

Contribution: short lecture

### **VAAM International Workshop 2008 „Biology and Chemistry of Antibiotic-Producing Bacteria“**

29.9.-01.10.2008

Berlin, Germany

Contribution: short lecture

## **10 Declaration on oath**

Herewith I confirm that I wrote the present thesis personally and independently and did not use any unnamed sources or aid.

I furthermore declare that I have not drawn up a previous PhD-thesis.

Frankfurt am Main, July 2014

Wolfram Lorenzen

## Erklärung

Ich erkläre hiermit, dass ich mich bisher keiner Doktorprüfung im Mathematisch-Naturwissenschaftlichen Bereich unterzogen habe.

Frankfurt am Main, den 09.07.2014

Wolfram Lorenzen

## Eidesstattliche Versicherung

Ich erkläre hiermit an Eides Statt, dass ich die vorgelegte Dissertation über

“IDENTIFICATION OF BIOMARKERS FOR THE FRUITING BODY FORMATION IN  
*MYXOCOCCUS XANTHUS*”

selbständig angefertigt und mich anderer Hilfsmittel als der in ihr angegebenen nicht bedient habe, insbesondere, dass alle Entlehnungen aus anderen Schriften mit Angabe der betreffenden Schrift gekennzeichnet sind.

Ich versichere, die Grundsätze der guten wissenschaftlichen Praxis beachtet, und nicht die Hilfe einer kommerziellen Promotionsvermittlung in Anspruch genommen zu haben.

Frankfurt am Main, den 09.07.2014

Wolfram Lorenzen
