23

24

25 **Abstract**

26   Omicron BA.1 variant isolates were previously shown to replicate less

27 effectively in interferon-competent cells and to be more sensitive to interferon

28 treatment than a Delta isolate. Here, an Omicron BA.2 isolate displayed intermediate

29 replication patterns in interferon-competent Caco-2-F03 cells when compared to BA.1

30 and Delta isolates. Moreover, BA.2 was less sensitive than BA.1 and similarly sensitive

31 as Delta to betaferon treatment. Delta and BA.1 displayed similar sensitivity to the

32 approved anti-SARS-CoV-2 drugs remdesivir, nirmatrelvir, EIDD-1931 (the active

33 metabolite of molnupiravir) and the protease inhibitor aprotinin, whereas BA.2 was

34 less sensitive than Delta and BA.1 to EIDD-1931, nirmatrelvir and aprotinin.

35 Nirmatrelvir, EIDD-1931, and aprotinin (but not remdesivir) exerted synergistic antiviral

36 activity in combination with betaferon, with some differences in the extent of synergism

37 detected between the different SARS-CoV-2 variants. In conclusion, even closely

38 related SARS-CoV-2 (sub)variants can differ in their biology and in their response to

39 antiviral treatments. Betaferon combinations with nirmatrelvir and, in particular, with

40 EIDD-1931 and aprotinin displayed high levels of synergism, which makes them

41 strong candidates for clinical testing. Notably, effective antiviral combination therapies

42 are desirable, as a higher efficacy is expected to reduce resistance formation.

43

46

Introduction

SARS-CoV-2, the coronavirus that causes COVID-19, has caused a pandemic starting in December 2019 [Forchette et al., 2021]. This pandemic has been driven by different SARS-CoV-2 variants that subsequently replaced each other. The original Wuhan strain, was replaced by the Alpha variant (B.1.1.7), which was later replaced by the Beta and P.1 variants in some parts of the world, before the Delta became the dominant variant [Forchette et al., 2021]. Most recently, the Omicron (B.1.1.529, BA.1) variant took over from Delta, which keeps evolving into further subvariants such as BA.2, BA.2.12.1, BA.3, BA.4, and BA.5 [Kawaoka et al., 2022; Sullivan et al., 2022].

SARS-CoV-2 evolution is at least in part driven by the selection pressure induced by previous infections and vaccinations. In agreement, Omicron subvariants display the greatest propensity to infect individuals with pre-existing vaccine- or infection-mediated immunity [Bruel et al., 2022; Quandt et al., 2022]. Despite this immune evasion capacity, the available vaccines, which are based on the original Wuhan strain, still provide significant protection from severe COVID-19 [Accorsi et al., 2022: Andrews et al., 2022].

There is also concern that new SARS-CoV-2 variants may change in their susceptibility to antiviral drugs. We have previously shown that SARS-CoV-2 and the closely related SARS-CoV differ in their drug sensitivity profiles [Bojkova et al., 2021]. However, different SARS-CoV-2 variants including Omicron BA.1 and BA.2 have so far displayed comparable sensitivity to the approved anti-SARS-CoV-2 drugs remdesivir (RNA-dependent RNA polymerase inhibitor), molnupiravir (induces 'lethal mutagenesis' during virus replication), and nirmatrelvir (inhibitor of the SARS-CoV-2 main/ 3CL protease) [Bojkova et al., 2022, Kawaoka et al., 2022; Takashita et al., 2022; Takashita et al., 2022b; Vangeel et al., 2022].

72   Host cell interferon signalling is crucial for the control of SARS-CoV-2

73   replication and avoiding severe COVID-19, as indicated by the high vulnerability of

74   individuals with defects in this innate immune response mechanism [Bastard et al.,

75   2020; Hadjadj et al., 2020; Zhang et al., 2020]. Despite this importance for SARS-

76   CoV-2 pathogenicity, interferons were not effective in initial clinical trials for the

77   treatment of COVID-19 [Bhushan et al., 2021; Li et al., 2021; Monk et al., 2021; WHO

78   Solidarity Trial Consortium, 2021]. However, we found that Omicron variant BA.1

79   isolates were substantially more sensitive to interferon treatment than a Delta isolate

80   [Bojkova et al., 2022a].

81   Based on these findings, we here systematically compared the sensitivity of

82   Delta, BA.1, and BA.2 isolates to betaferon (a clinically approved interferon-β

83   preparation) alone or in combination with the approved anti-SARS-CoV-2 drugs

84   remdesivir, molnupiravir, and nirmatrelvir [Ho et al., 2022]. Moreover, we included

85   aprotinin in this study, a protease inhibitor that we have shown to inhibit SARS-CoV-2

86   replication at least in part by interfering with the cleavage and activation of the viral

87   spike (S) protein by host cell proteases [Bojkova et al., 2020; Bojkova et al., 2022] and

88   that was recently reported to be effective in COVID-19 patients in a clinical trial

89   [Redondo-Calvo et al., 2022].

90

91

4

92   **Methods**

93   **Analysis of sequence variants**

94   Amino acid sequences of the SARS-CoV-2 isolates FFM-SIM0550 (Omicron

95   BA.1, GenBank ID: OL800702), FFM-BA.2-3833 (Omicron BA.2, GenBank ID:

96   OM617939), and FFM-IND8424 (Delta/ B.1.617.2, GenBank ID: MZ315141) were

97   obtained and aligned using the NCBI Virus tool

98   (https://www.ncbi.nlm.nih.gov/labs/virus/). The mutation prevalence in these isolates

99   was compared to their prevalence across the lineage using https://www.outbreak.info.

100   The potential significance of individual mutations was assessed relative to the

101   Wuhan reference strain by determining Blosum80 scores

102   (https://www.rdocumentation.org/packages/peptider/versions/0.2.2/topics/BLOSUM8

103   0), evolutionary conservation using ConSurf [Ashkenazy et al., 2016], and the potential

104   impact of mutation on protein stability using the mCSM-PPI2 server [Rodrigues et al.,

105   2019].

106   Changes to residue bonding were visualised using Covid-3D [Portelli et al.,

107   2020] and Pymol (https://pymol.org/2/). Annotated protein structures were created

108   from existing structures obtained from the Protein Databank in Europe (PDBe) [PDBe-

109   KB consortium, 2022] Covid-19 data portal (https://www.ebi.ac.uk/pdbe/covid-19) or

110   modelled using AlphaFold [Jumper et al., 2021].

111

112   **Cell culture**

113   The Caco-2 subline Caco-2-F03 [Cinatl et al., 2004; Hoehl et al., 2020; Bojkova

114   et al., 2021; Bojkova et al., 2022b] (derived from the Resistant Cancer Cell Line

115   (RCCL) collection [Michaelis et al., 2019]), Vero (DSMZ, Braunschweig, Germany),

116   Calu-3 (ATCC, Manassas, VA, US) were grown at 37 °C in minimal essential medium

117   (MEM) supplemented with 10% fetal bovine serum (FBS), 100 IU/mL of penicillin, and

118   100 µg/mL of streptomycin. All culture reagents were purchased from Sigma-Aldrich.

119

120   **Virus preparation**

121   The SARS-CoV-2 isolates Omicron BA.1 (B.1.1.529: FFM-SIM0550/2021,

122   EPI_ISL_6959871, GenBank ID OL800702), Omicron BA.2 (B.1.1.529.2: FFM-BA.2-

123   3833, GenBank ID OM617939), and Delta (B.1.167.2: FFM-IND8424/2021, GenBank

124   ID MZ315141) were cultivated in Caco-2 cells as previously described [Cinatl et al.,

125   2004; Hoehl et al., 2020; Bojkova et al., 2021] and stored at –80°C.

126

127   **Determination of infectious titres**

128   Caco-2-F03 cells were infected with SARS-CoV-2 variants at MOI of 1 for 1h.

129   After the incubation period, the infectious inoculum was removed, cells were washed

130   with PBS and supplemented with fresh medium. One day later, supernatants were

131   collected and stored at -80°C upon titration. Infectious titres were determined by serial

132   dilutions of cell culture supernatants on confluent layers of Caco-2 cells in 96-well

133   plates and expressed as TCID50/ml.

134

135   **Immunofluorescence staining**

136   The cells were fixed at indicated times with 3% PFA permeabilized with 0.1 %

137   Triton X-100. Prior to primary antibody labeling, cells were blocked with 5% donkey

138   serum in PBS or 1% BSA and 2% goat serum in PBS for 30 minutes at RT. Spike

139   protein was detected by primary antibody (1:1500, Sinobiological) followed by Alexa

140   Fluor 647 anti-rabbit secondary antibody (1:1000, Invitrogen). The nucleus was

141   labelled using DAPI (1:1000, Thermo Scientific). The images were taken by Spark®

142   Mulitmode microplate reader (TECAN) at 4x magnification.

143

Immunostaining

145   Cells were fixed with acetone:methanol (40:60) solution and immunostaining

146   was performed using a monoclonal antibody directed against the spike protein of

147   SARS-CoV-2 (1:1500, Sinobiological), which was detected with a peroxidase-

148   conjugated anti-rabbit secondary antibody (1:1000, Dianova), followed by addition of

149   AEC substrate. The spike positive area was scanned and quantified by the Bioreader®

150   7000-F-Z-I microplate reader (Biosys). The results are expressed as percentage of

151   inhibition relative to virus control which received no drug.

152

Antiviral assay

154   Confluent layers of cells in 96-well plates were treated with decreasing

155   concentrations of interferon-β (betaferon, Bayer), remdesivir (Selleckchem),

156   nirmatrelvir (Selleckchem), molnupiravir (Selleckchem) and/ or aprotinin (Sigma-

157   Aldrich) subsequently infected with SARS-CoV-2 at an MOI of 0.01. In experiments

158   with remdesivir and nirmatrelvir, 1 µM of the ABCB1 inhibitor Zosuquidar

159   (Selleckchem) was added. Antiviral effects were determined by immunostaining for

160   the SARS-CoV-2 spike (S) protein 24 h post infection.

161   To evaluate antiviral activity of interferon-β in a combination with remdesivir,

162   nirmatrelvir, EIDD-1931 (Selleckchem), or aprotinin the agents were tested alone or

163   in fixed combinations at 1:2 dilutions using monolayers of Caco-2 cells infected SARS-

164   CoV-2 isolates at MOI 1 24 h post infection. The calculation of IC_{50}, IC_{75}, IC_{90} and IC_{95}

165   for single drugs and their combinations as well as combination indexes (CIs) was

166   performed using the software CalcuSyn (Biosoft) based on the method of Chou and

167   Talalay [Chou, 2006]. The weighted average CI value (CI_{wt}) was calculated according

168   to the formula: CI_{wt} [CI_{50} + $2CI_{75}$ + $3CI_{90}$ + $4CI_{95}$]/10. CI_{wt} values were calculated for

169   mutually exclusive interactions where CI_{wt} <1 indicates synergism, CI_{wt} =1 indicates

170   additive effects, and CI_{wt} >1 suggest antagonism.

171

172   **Quantification of SARS-CoV-2 RNA**

173   Quantification of SARS-CoV-2 RNA was performed as previously described

174   [Toptan et al., 2020]. SARS-CoV-2 RNA from cell culture supernatant samples was

175   isolated using AVL buffer and the QIAamp Viral RNA Kit (Qiagen) according to the

176   manufacturer's instructions. Intracellular RNAs were isolated using the RNeasy Mini

177   Kit (Qiagen) as described by the manufacturer. RNA was subjected to OneStep qRT-

178   PCR analysis using the Luna Universal One-Step RT-qPCR Kit (New England

179   Biolabs) or Luna Universal Probe One-Step RT-qPCR Kit (New England Biolabs) or

180   LightCycler® Multiplex RNA Virus Master (Roche) using the CFX96 Real-Time

181   System, C1000 Touch Thermal Cycler. The primer pairs for the E-, S- and M-gene-

182   specific PCRs were used in equimolar concentrations (0.4 µM each per reaction). The

183   RdRP primer pairs were used according to Corman et al. [Corman et al., 2020] with

184   0.6 µM and 0.8 µM concentrations of the forward and reverse primers, respectively.

185   The cycling conditions were used according to the manufacturer's instructions. Briefly,

186   for SYBR green-and probe-based Luna Universal One-Step RT-qPCR Kits, 2 µL of

187   RNA was subjected to a reverse transcription reaction in a reaction volume of 20 µL,

188   performed at 55 °C for 10 min. Initial denaturation was performed for 1 min at 95 °C,

189   followed by 45 cycles of denaturation for 10 s and extension for 30 s at 60 °C. Melt

190   curve analysis (SYBR green) was performed from 65–95 °C with an increment of 0.5

8

191   °C each 5 s. For the IVD-approved LightCycler® Multiplex RNA Virus Master (Roche),

192   5 µL of template RNA in a total reaction volume of 20 µL was used. Reverse

193   transcription was performed at 55 °C for 10 min. Initial denaturation was induced for

194   30 s at 95 °C, followed by 45 cycles of denaturation for 5 s at 95 °C, and extension for

195   30 s at 60 °C, and a final cool-down to 40 °C for 30 s. The PCR runs were analysed

196   with the Bio-Rad CFX Manager software, version 3.1 (Bio Rad Laboratories).

197

198   **Cell viability**

199   Cell viability was determined using the CellTiter-Glo® Luminescent Cell Viability

200   Assay (Promega) according to the manufacturer's instructions.

201

202   **Statistics**

203   The results are expressed as the mean ± standard deviation (SD) of the number

204   of biological replicates indicated in figure legends. The statistical significance is

205   depicted directly in graphs and the statistical test used for calculation of p values is

206   indicated in figure legends. GraphPad Prism 9 was used to determine IC50 values.

207

208   **Results**

209   **Sequence differences in the interferon antagonists between Delta, Omicron**

210   **BA.1, and Omicron BA.2**

211   We have previously shown that Omicron BA.1 virus isolates display higher

212   sensitivity to interferons than a Delta isolate [Bojkova et al., 2022b]. Sequence

213   differences in a range of putative viral interferon antagonists may be responsible for

214   this [Bojkova et al., 2022b].

215   Here, a comparison of sequence variants in a Delta, an Omicron BA.1, and an

216   Omicron BA.2 virus isolate identified 96 sequence variants in putative interferon

217   antagonists that differed from the reference genome of the original Wuhan strain

218   (Suppl. Table 1).

219   Only three sequence variants were shared between all three isolates (Figure

220   1A). The overlap in sequence variants between BA.1 and BA.2 was larger (49) than

221   between Delta and BA.1 (21) and Delta and BA.2 (18). Moreover, Delta displayed

222   more unique sequence variants (54) in the putative interferon antagonists than BA.1

223   (23) or BA.2 (26) (Figure 1A).

224

Figure 1
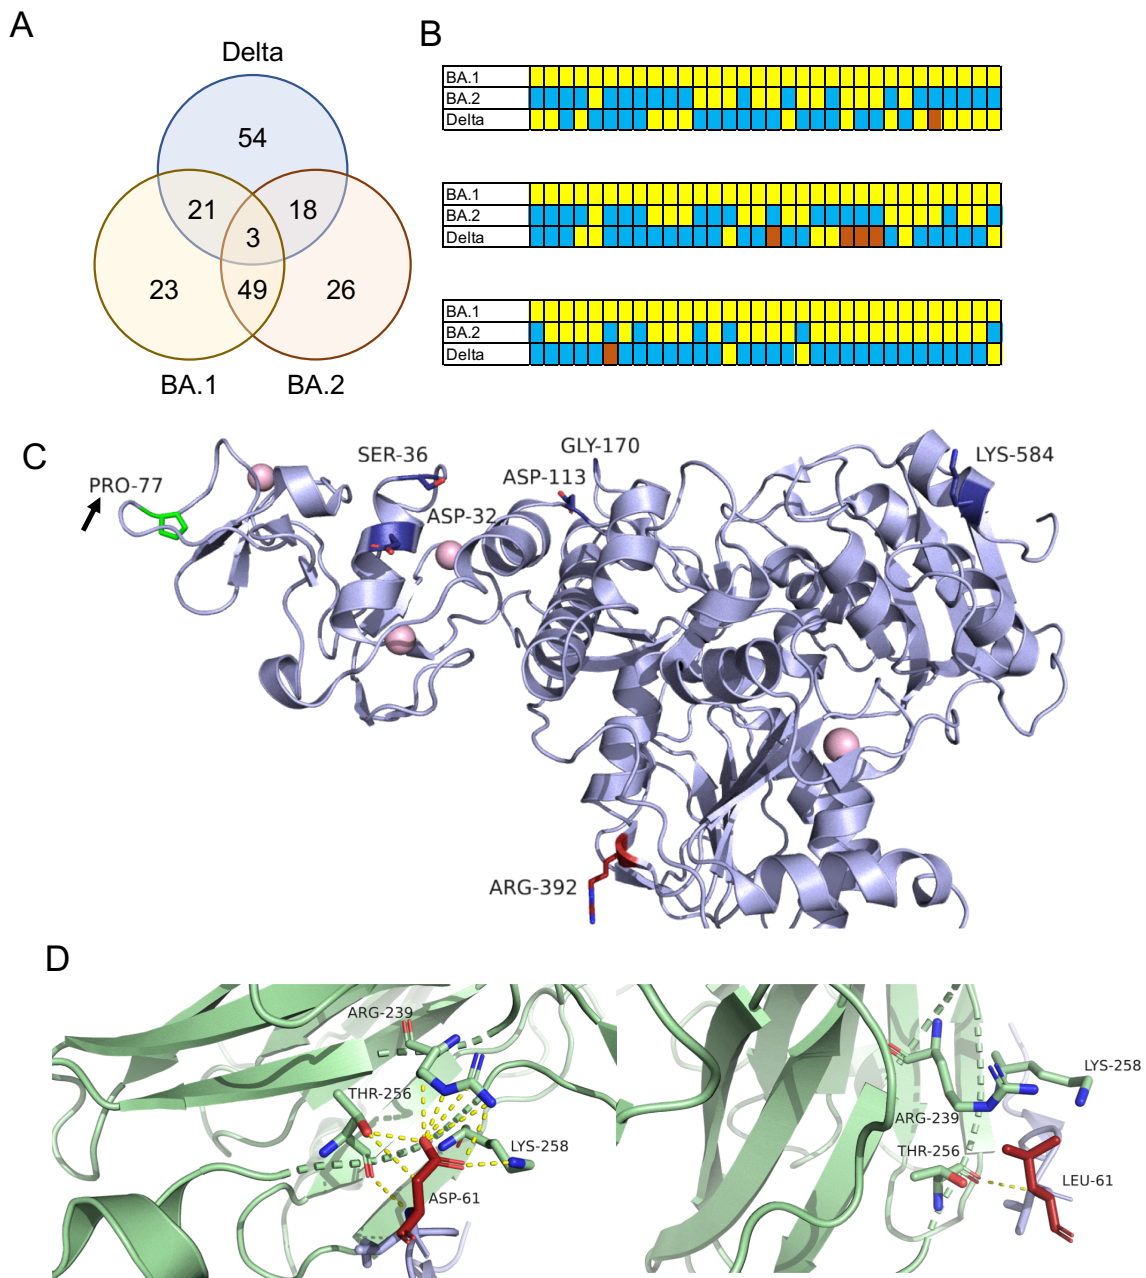

Figure 1. Sequence variants that may contribute to differences in the response to interferon treatment Omicron BA.1, Omicron BA.2, and Delta isolates. A) Overlaps between sequence variants in putative SARS-CoV-2 interferon antagonists determined in BA.1 (FFM-SIM0550/2021, GenBank ID: OL800702), BA.2 (FFM-BA.2-3833, GenBank ID: OM617939), and Delta (FFM-IND8424/2021, GenBank ID: MZ315141) isolates. B) A heatmap illustrating the differences in amino acid residues

232 in SARS-CoV-2 proteins anticipated to be of potential relevance for interferon

233 signalling between the SARS-CoV-2 isolates (differences in colour indicate different

234 residues). C) Key residues of NSP13 thought to antagonise interferon signalling via

235 interaction with TBK1. Only the Delta isolate is harbouring a P77L (proline/ Pro to

236 leucine/ Leu) change (highlighted by an arrow), which has been proposed to affect the

237 interaction of NSP13 and TBK1 [Rashid et al., 2021]. Source PDB structure 7re2. D)

238 ORF6 antagonises the cellular interferon response by direct interaction of its C-

239 terminal domain with the RNA binding pocket of the Nup98-Rae1 complex [Miorin et

240 al., 2020; Kato et al., 2021]. While BA.1 and Delta harbour leucine (L/ Leu) in position

241 61, BA.2 harbours an aspartate (D/ Asp) in this position. The number of hydrogen

242 bonds between ORF6 and Rae1 is anticipated to be strongly reduced when aspartate

243 (left image) is replaced by leucine (right image). The resulting reduced complex

244 stability is likely to modify the capacity of ORF6 to suppress the cellular interferon

245 response. Source PDB structure 7vph.

246

247 These findings appear to reflect the closer relatedness of BA.1 and BA.2

248 relative to Delta. However, the variant overlaps are complex (Figure 1B), and it is not

249 clear, which of them drive the virus response to interferons.

250 45 of the 96 sequence variants could be modelled on protein structures or

251 models (Suppl. File 1). However, it was difficult to draw reliable conclusions. Many of

252 the mutations were in the Spike (S) protein, for which detailed information on its role

253 as interferon antagonist is lacking (Suppl. Table 1, Suppl. File 1).

254 There are only two sequence variants that are likely to modify interferon

255 signalling. NSP13 inhibits the activation of an interferon response by physically

256 interacting with the TANK binding kinase 1 (TBK1), which, prevents the

257 phosphorylation, dimerisation, and nuclear translocation of the interferon regulatory

258 factors 3 and 7 (IRF3, IRF7). In contrast to BA.1 and BA.2, the Delta isolate harbours

259 a P77L change in NSP13 (Figure 1C, Suppl. Table 1, Suppl. File 1). This proline (P)

260 to leucine (L) change is likely to have an impact, as a proline at this position has been

261 proposed to be crucial for the NSP13-TBK1 interaction [Rashid et al., 2021].

262 Moreover, BA.2 harbours in contrast to BA.1 and Delta a D61L sequence

263 variant in ORF6 (Figure 1C, Suppl. Table 1, Suppl. File 1), which has been shown to

264 antagonise the cellular interferon response by inhibiting the nuclear translocation of

265 STAT1 and STAT2 through direct interaction of its C-terminal domain with the RNA

266 binding pocket of the Nup98-Rae1 complex [Miorin et al., 2020; Kato et al., 2021].

267 This aspartic acid (D) to leucine (L) change at position 61 in the C-terminal

268 domain has the potential to be significant, as the number of hydrogen bonds formed

269 between ORF6 and Rae1 is predicted to be strongly reduced when the aspartate is

270 replaced by a leucine (Figure 1D).

271 Taken together, sequence differences between the SARS-CoV-2 interferon

272 antagonists in BA.1, BA.2, and Delta warrant the further comparison of these three

273 SARS-CoV-2 variants for their responses to interferon treatment.

274

275 **Replication kinetics of Delta, Omicron BA.1, and Omicron BA.2 in Caco-2 cells**

276 Previously, we have shown that a Delta isolate infects a higher proportion of

277 cells and replicates to higher titres in Caco-2-F03 cells (a Caco-2 subline that is highly

278 susceptible to SARS-CoV-2 infection [Bojova et al., 2022b]) than two Omicron BA.1

279 isolates [Bojkova et al., 2022; Bojkova et al., 2022a]. Here, these results were

280 confirmed (Figure 2A-C). BA.2 (GenBank ID OM617939) replicated more effectively

281 than BA.1 but less effectively than Delta in Caco-2 cells (Figure 2-C).

13

282

283
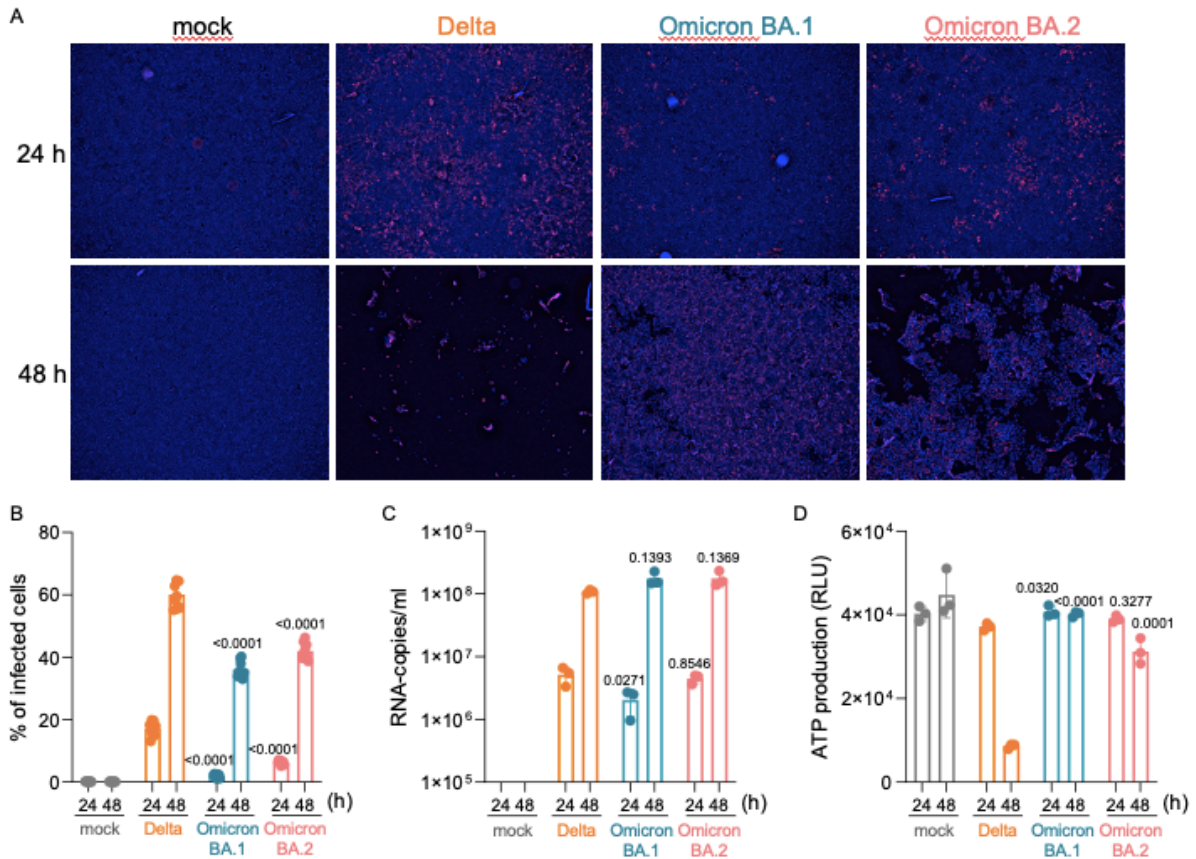

Figure 2. Replication kinetics of SARS-CoV-2 Delta, Omicron BA.1, and Omicron BA.2 isolates in Caco-2 cells. A) Representative immunofluorescence images indicating the number of Spike (S) protein-positive Caco-2-F03 cells 24h and 48h post infection with Delta, BA.1, and BA.2 at an MOI of 1. B) Quantification of S protein-positive Caco-2-F03 cells 24h and 48h post infection with Delta, BA.1, and BA.2 at an MOI of 1. C) Genomic RNA copy numbers determined by qPCR 24h and 48h post infection of Caco-2 cells with Delta, BA.1, and BA.2 at an MOI of 1. D) Cell viability in Caco-2-F03 cells 24h and 48h post infection as determined by CellTiter-Glo® Luminescent Cell Viability Assay (Promega). Values represent mean ± S.D. of three independent experiments. P-values represent statistical differences between Delta and BA.1 or BA.2 calculated by one-way ANOVA and Tukey's test.

295

14

296

297

298   These differences in the replication kinetics (Delta > BA.2 > BA.1) were also

299   reflected in cytopathogenic effect (CPE) formation (Figure 2A) and cell viability

300   measurements (Figure 2D).

301

302   **Delta, Omicron BA.1, and BA.2 sensitivity to approved antiviral drugs**

303   Next, we tested the effects of the approved anti-SARS-CoV-2 drugs remdesivir,

304   EIDD-1931 (the active metabolite of the prodrug molnupiravir), and nirmatrelvir (the

305   antivirally active agent in Paxlovid) on Delta, BA.1, and BA.2 replication. All three

306   isolates displayed similar sensitivity to all three drugs (Figure 3A, 3B).

307
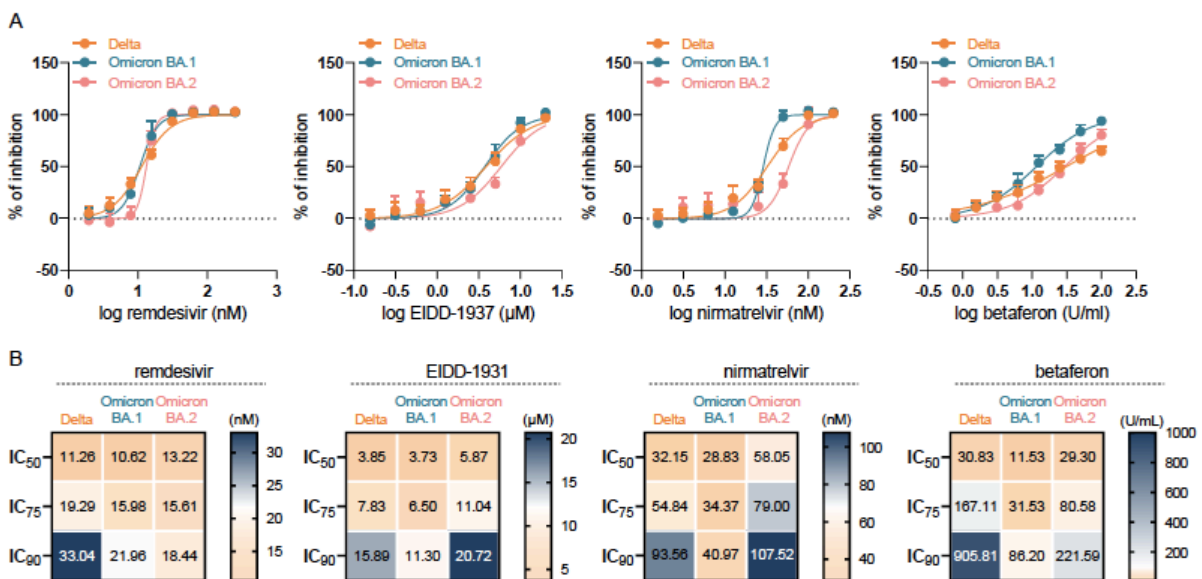

308

309   **Figure 3. Delta, Omicron BA.1, and Omicron BA.2 isolate sensitivity to antiviral**

310   **drugs.** A) Dose response curves and B) concentrations that reduce the number of

311   Spike (S)-protein positive cells by 50% (IC_{50}), 75% (IC_{75}), and 90% (IC_{90}) in Caco-2-

312   F03 cells infected with the different SARS-CoV-2 isolates at an MOI 1 24 h post

313   infection, as determined by immunostaining.

314

315   We had previously shown that BA.1 is more sensitive to interferon-β than Delta

316   [Bojkova et al., 2022b]. This time, we used the clinically approved interferon-β

317   preparation betaferon (Bayer) for our experiments. In agreement with the previous

318   data, betaferon was more effective against BA.1 than against Delta (Figure 3A, 3B).

319   Interestingly and perhaps unexpectedly, the betaferon response of BA.2 more closely

320   resembled that of Delta and not that of the more closely related BA.1 (Figure 3A, 3B).

321   This confirmed our previous findings (Figure 1) that the impact of amino acid sequence

322   differences in different SARS-CoV-2 isolates on the viral interferon response is not

323   easily predictable and can differ even between closely related virus variants.

324

Effects of betaferon in combination with approved anti-SARS-CoV-2 drugs

326   Since our previous findings had shown that interferon-β displayed different

327   levels of synergism with remdesivir, EIDD-1931, and nirmatrelvir [Bojkova et al.,

328   2022a], we further tested betaferon in combination with these drugs.

329   Results were comparable to the previous findings [Bojkova et al., 2022b].

330   Remdesivir displayed additive to moderately synergistic effects in combination with

331   betaferon against all three variants (Figure 4). While EIDD-1931 and nirmatrelvir

332   treatment resulted in similar levels of synergism with betaferon against Delta,

333   combined EIDD-1931 and interferon treatment was associated with a more

334   pronounced synergism against BA.1 and BA.2 than the combination of nirmatrelvir

335   and betaferon (Figure 4).

336

16
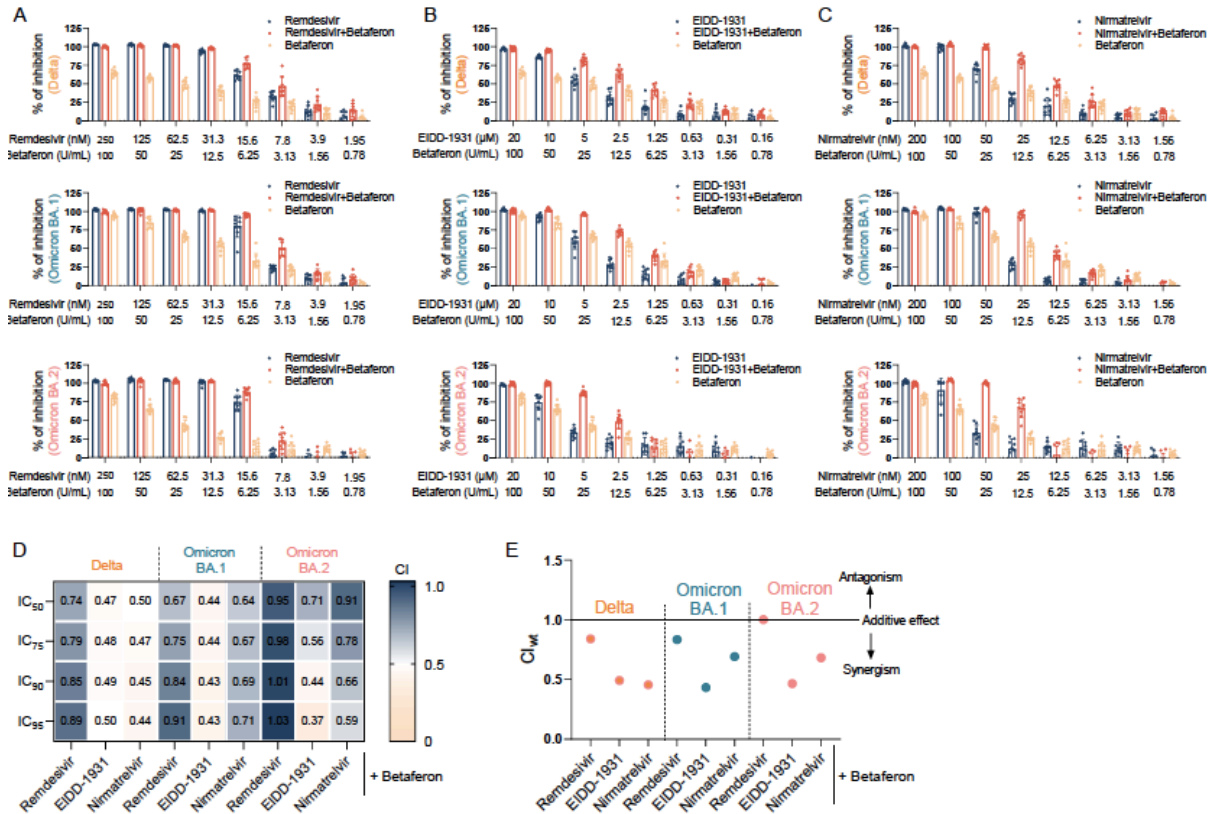

Figure 4. Antiviral effects of approved anti-SARS-CoV-2 drugs in combination with interferon-β (betaferon) against Delta, Omicron BA.1, and Omicron BA.2 isolates. Betaferon was tested in fixed combinations combination with remdesivir (A), EIDD-1931 (B), or nirmatrelvir (C) in SARS-CoV-2 (MOI 0.01)-infected Caco-2-F03 cells. Values represent mean ± S.D. of three independent experiments. D) Combination indices were calculated at the IC_{50}, IC_{75}, IC_{90}, and IC_{95} levels following the method of Chou and Talalay [Chou, 2006]. E) The weighted average CI value (CI_{wt}) was calculated according to the formula: CI_{wt} [CI_{50} + $2CI_{75}$ + $3CI_{90}$ + $4CI_{95}$]/10. A CI_{wt} <1 indicates synergism, a CI_{wt} =1 indicates additive effects, and a CI_{wt} >1 suggest antagonism.

349 **Effects of betaferon in combination with the antiviral protease inhibitor aprotinin**

350   Previously, we have shown that the protease inhibitor aprotinin inhibits

351 replication of the SARS-CoV-2 original Wuhan strain at least in part by inhibition of the

352 cleavage and activation of the viral spike (S) protein by host cell proteases [Bojkova

353 et al., 2020]. Based on these findings, a clinical trial was initiated that reported

354 improved outcomes of COVID-19 patients treated with an aprotinin aerosol [Redondo-

355 Calvo et al., 2022]. Among other improvements, aprotinin treatment reduced the

356 length of hospital stays by five days [Redondo-Calvo et al., 2022].

357   Here, we show that aprotinin inhibits Delta (IC50: 0.66µM) and BA.1 (IC50:

358 0.64µM) in a similar concentration range as the original Wuhan strain isolates [Bojkova

359 et al., 2020] (Suppl. Figure 1). Effects against BA.2 were less pronounced (IC50:

360 1.95µM) but still in the range of clinically achievable plasma concentrations after

361 systemic administration, which have been described to reach 11.8µM [Levy et al.,

362 1994; Bojkova et al., 2020]. Moreover, aerosol preparations like the one used in the

363 clinical trial that demonstrated therapeutic efficacy of aprotinin against COVID-19

364 [Redondo-Calvo et al., 2022] are expected to result in substantially higher aprotinin

365 concentrations locally in the lungs.

366   Interestingly, aprotinin displayed a strong synergism with betaferon against

367 Delta and an even much stronger synergism against BA.1 and BA.2 (Figure 5).

368

Figure 5
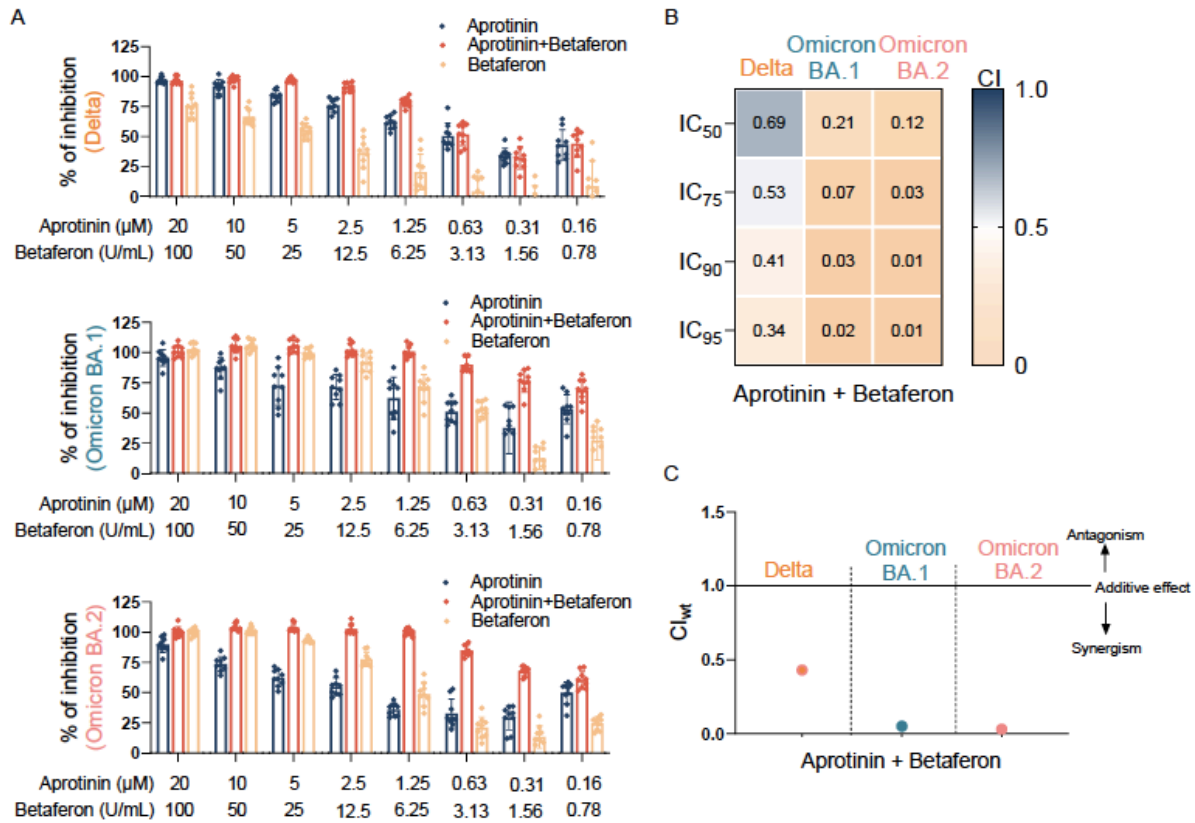

Figure 5. Antiviral effects of aprotinin in combination with interferon-β (betaferon) against Delta, Omicron BA.1, and Omicron BA.2 isolates. Betaferon was tested in a fixed combination with aprotinin in SARS-CoV-2 (MOI 0.01)-infected Caco-2-F03 cells. Values represent mean ± S.D. of three independent experiments. B) Combination indices were calculated at the IC_{50}, IC_{75}, IC_{90}, and IC_{95} levels following the method of Chou and Talalay [Chou, 2006]. C) The weighted average CI value (CI_{wt}) was calculated according to the formula: CI_{wt} $[CI_{50} + 2CI_{75} + 3CI_{90} + 4CI_{95}]/10$. A $CI_{wt} <1$ indicates synergism, a $CI_{wt} =1$ indicates additive effects, and a $CI_{wt} >1$ suggest antagonism.

Discussion

Previously, we found that Omicron BA.1 variant isolates induce a stronger interferon response and replicate less effectively in interferon-competent cells than a Delta isolate. Moreover, BA.1 isolates were more sensitive to interferon treatment than a Delta isolate [Bojkova et al., 2022; Bojkova et al., 2022a]. Here, we show that an Omicron BA.2 isolate displays intermediate replication patterns in interferon-competent Caco-2-F03 cells when compared to BA.1 and Delta isolates. Moreover, BA.2 is less sensitive than BA.1 and similarly sensitive as Delta to betaferon treatment.

The reasons for these differences are not obvious. The sequence differences in the putative viral interferon antagonists are complex. There are two sequence variants for which there is plausible evidence that they may impact on the viral interferon sensitivity based on an *in silico* structural analysis. The Delta isolate harbours a P77L change in NSP13 that is likely to have an impact on TBK1-mediated interferon signalling [Rashid et al., 2021]. Additionally, BA.2 harbours in contrast to BA.1 and Delta a D61L sequence variant in ORF6 that may modify the potential of ORF6 to antagonise the cellular interferon response [Miorin et al., 2020; Kato et al., 2021]. However, these changes are probably just small pieces in a large puzzle of virus protein interactions with the complex regulatory networks that determine the cellular interferon response [Blalock, 2021].

Delta and BA.2 displayed similar sensitivity to the approved anti-SARS-CoV-2 drugs remdesivir, nirmatrelvir, and EIDD-1931 (the active metabolite of molnupiravir), whereas BA.2 was less sensitive to EIDD-1931 than Delta and BA.1. Moreover, BA.2 was less sensitive than BA.1 and Delta to aprotinin, a protease inhibitor that was previously shown to inhibit the original SARS-CoV-2 Wuhan strain and demonstrated

405   clinical efficacy in COVID-19 patients [Bojkova et al., 2020; Redondo-Calvo et al.,

406   2022].

407   When we investigated these four drugs in combination with betaferon, only

408   betaferon combinations with nirmatrelvir, EIDD-1931, and aprotinin resulted in

409   synergistic activity. We also detected variant-specific differences. While nirmatrelvir

410   and EIDD-1931 showed similar synergy with betaferon against Delta, the betaferon/

411   EIDD-1931 synergism was more pronounced than the betaferon/ nirmatrelvir

412   synergism against BA.1 and BA.2. Aprotinin displayed the strongest synergism with

413   betaferon against BA.1 and BA.2 among all tested drugs. Against Delta, the level of

414   synergism of aprotinin/ betaferon was similar to that of EIDD-1931/ betaferon. Given

415   the differences between the SARS-CoV-2 (sub)variants, our data suggest that an

416   improved understanding of the combined effects of antiviral drugs on certain SARS-

417   CoV-2 variants can inform the design of optimised combination therapies.

418   Effective antiviral combination therapies are anticipated to be of crucial

419   importance for the control of virus outbreaks, as a higher efficacy is expected to

420   decrease or even prevent resistance formation [White et al., 2021]. So far, clinical

421   studies reported mixed outcomes in patients treated with remdesivir/ interferon

422   combinations [Kalil et al., 2021; Tam et al., 2022]. This may not be too surprising in

423   the light of our current findings, suggesting that combining betaferon with nirmatrelvir,

424   molnupiravir, and aprotinin is more promising than with remdesivir.

425   In conclusion, even closely related SARS-CoV-2 (sub)variants can differ in their

426   biology, as indicated by different BA.1 and BA.2 replication kinetics, and in their

427   response to antiviral treatments, as indicated by differences in the virus responses to

428   betaferon, EIDD-1931/ molnupiravir, and aprotinin and differing levels of synergism of

429   betaferon combinations with other antiviral drugs. Betaferon combinations with

430   nirmatrelvir and, in particular, with EIDD-1931 and aprotinin displayed high levels of

431   synergism, which makes them strong candidates for clinical testing.

709 **modelled on protein structures and models.**

710

711

712 **ORF1ab polyprotein.**

713 *Nsp1.*

714 Model shown is from COVID-3D as no PDB structures exist that contain the residue

715 of interest.

716

717 BA.2 mutation S135R. Serine to Arginine.

718 Blosum score of -1. Polar uncharged to positively charged.

719 ConSurf score of 1. Highly variable residue.

720 $\Delta\Delta G^{stability}$ mCSM: -0.58 kcal.mol^{-1} (destabilising).

721 This mutation is present in 98.1% of all BA.2 sequences.

722

723   Nsp1 has a globular N-terminal domain, a short linking domain, and a C-

724 terminal helix-turn-helix motif. Its C-terminal binds to the mRNA entry channel of 40S

725 ribosomal subunits, blocking host translation including interferons and ISGs (1).

726

727   Ser-135 is located in the linking domain and does not form bonds with residues

728 within the C-terminal domain. There is one polar bond connecting Ser-135 to the

729 globular domain which is unaltered upon mutation, and it does not appear to be

730 providing stability to the C-terminal domain. Given the high variability of this residue it

731 is likely that the mutation is inconsequential.

732
733

734 **Fig 1: Cartoon of nsp1.** The N-terminal globular domain is in the upper part of the

735 image. Linking domain is highlighted in light blue, Ser-135 in red. The C-terminal

736 domain is in the lower part of the image. Source structure 3-D Covid (2).

737

738

739   *Nsp3: PL-pro.*

740

741   PDB structure 6xa9.

742

743   Delta Mutation. P77L. Proline to Leucine.

744   Blosum score of -3. Special case to hydrophobic.

745   ConSurf score of 3. Moderately variable residue.

746   $\Delta\Delta G^{stability}$ mCSM: -0.24 kcal/mol^{-1} (Destabilising).

747   This mutation is only present in 9.1% of all Delta sequences.

748

749   PLpro is a domain of nsp3 with protease activity. This PDB structure has

750   assembled PLpro as a homotrimer, but it is shown below as a monomer in association

751   with ISG15. Pro-77 is located at the end of an alpha helix, on a turn. It is likely to be

752   providing rigidity to this part of the structure. mCSM predicts this is a destabilising

753   mutation, and that Pro-77 loses a polar and a hydrogen bond to surrounding residues

754   on mutation. However, Pro-77 is located some distance from two binding areas,

755   described as fingers and thumb (mainly composed of sections of beta-sheets).

756
757

758   **Figure 2**. Cartoon representation of PLpro, monomeric form. Pro-77 is highlighted in

759   green. Source PDB structure 7cjm.

760

761   PLpro has been shown to cleave ISG15, and its enzymatic activity appears to

762   be essential to its inhibitory activity against Type I IFN responses (3). Two structures

763   showing alternative bindings of PLpro with ISG15 are shown below. mCSM-PPI2

764   predicted no change in affinity between the two proteins on mutation. However, since

765   mCSM predicted a decrease in structural stability, there could be an implication on

766   binding with ISG15, either increasing or decreasing affinity between the two proteins.
767

768   **Figure 3. PLpro in association with ISG15.** ISG15 (light green chain) associates

769   with the thumb area of PLpro, which is the same region where small molecule

770   inhibitors associate. In the image above, the binding pocket has been rendered with a

771   surface to show distance from Pro-77 (highlighted in green). Source PDB structure

772   6xa9.

773

774
Figure 4. PLpro in association with ISG15, alternative binding. Residues Ala-2, Thr-20 and Met-23 of ISG15 (light green) form a hydrophobic patch, which mediates the association with PLpro. The key residues on PL-pro, where mutation to Alanine decreases binding to ISG15 and enzymatic activity are Thr-75 and Phe-69 (deep blue) . Pro-77 (bright green) is positioned a short distance along the loop from these residues, away from the hydrophobic patch. Source PDB structure 6yva.

786
787
788

789 *Nsp5: 3CLpro.*
790 PDB structure 7lmc.

791

792   BA.1/BA.2 Mutation. P132H. Proline to Histidine.

793   Blosum score of -2. Special case to positively charged.

794   ConSurf score of 3. Moderately variable residue.

795     $\Delta\Delta G^{stability}$ mCSM: -1.77 kcal/mol^{-1} (Destabilising).

796   This mutation is present in 98.1% of all BA.1 sequences and 99.4% of BA.2

797   sequences.

798

799   Numerous model structures exist with multiple ligands - mostly inhibitors. There

800   is consensus that dimerisation of 3CLpro is essential to stabilise the conformation of

801   the catalytic site.

802

803   Pro-132 is situated on a turn, and is located away from binding/catalytic sites

804   (Fig 5-8), and opposite to the plane where the protomers associate with one another

805   (Fig 5). Blosum score is low, but perhaps because both residues contain a cyclic

806   compound, the effect of removing a proline from this loop position might be lessened.

807   Modelling mutagenesis in Pymol shows that all 9 rotamers of Histidine create multiple

808   clashes with surrounding residues, which may be why mCSM predicts this as a

809   destabilising mutation.

810

811   The enzymatic (cysteine protease) activity of 3CLpro was described to be

812   essential for the inhibition of interferon induction (4). Both RIG-I and NEMO are

813   potential cleavage targets of 3CLpro (4,5). Since the protease activity of 3CLpro is so

814   important to viral replication, it seems unlikely that this mutation has much significance.

815

816
Figure 5. 3CLpro assembled as a homodimer. Cartoon representation of 3CLpro. Protomers are coloured light blue and light green. Pro-132 is highlighted in red. Source PDB structure 7bb2.

820
Figure 6. 3CLpro in association with the C-terminal of nsp4. Cartoon representation of 3CLpro in monomeric form. The C-terminal of nsp4 is highlighted in pink, whilst Pro-132 is highlighted in red. The binding site for nsp4 appears to also be the catalytic site of 3CLpro. Pro-132 is some distance from this site. Source PDB structure 7lmc.

826
827

828 **Figure 7. 3CLpro in association with small molecule inhibitor GRL2420.** Cartoon

829 representation of 3CLpro. The small molecule inhibitor GRL2420 is highlighted in

830 magenta. This binding pocket appears constant for multiple small molecule inhibitors

831 and the C-terminal of nsp4. This area is associated with conserved residues across

832 all coronaviruses, essential to its enzymatic activity (6). Source PDB structure 7jkv.

833

834
835

836 **Figure 8. 3CLpro in association with Pelitinib, which binds to the allosteric**

837 **dimerisation domain.** Cartoon representation of 3CLpro. Pelitinib is highlighted in

838 pink. This small molecule inhibitor binds to a hydrophobic patch thought to be a

839 dimerisation domain (7). This site appears to be distant from Pro-132. Source PDB

840 structure 7axm.

841

842

843 *Nsp12: RNA-dependent RNA polymerase.*

844 PDB structure 7b3b.

845

846 BA.1/BA.2/Delta Mutation. P323L. Proline to Leucine.

847 Blosum score of -3. Special case to hydrophobic.

848 ConSurf score of 1. Highly variable residue.

849 $\Delta\Delta G^{stability}$ mCSM: -0.29 kcal/mol^{-1} (Destabilising).

850 This mutation is present in 99.0% of all Delta, 98.7% of all BA.1 and 99.4% of all BA.2

851 sequences.

852

853 Delta Mutation. G671S: Glycine to Serine.

854 Blosum score of 0. Special case to polar uncharged.

855 Consurf score of 8. Highly conserved residue.

856 $\Delta\Delta G^{stability}$ mCSM: -0.97 kcal/mol^{-1} (Destabilising).

857 This mutation is present in 97.5% of all Delta sequences.

858

859   This structure is often modelled with nsp7 and nsp8, and on occasion with

860 nsp13. Here, monomeric form is shown with RNA and remdesivir bound to show active

861 sites.

862   Nsp12 has a Nidovirus RdRp-associated nucleotidyltransferase (NiRNA)

863 domain (1-249), and a right hand RdRp domain (365-932), connected by an interface

864 domain (249-365).

865   The catalytic residues in the RdRp domain are SDD (759-761), and the GDD

866 motif (823-825) which is catalytic in other viral RdRps (8).

867

868   Importantly, there are mixed reports on nsp12's IFN antagonistic activity.

869   It has been reported that nsp12 inhibits nuclear translocation of IRF3, and that

870   this is not dependent on either the RdRp enzymatic activity or the NiRNA domain, nor

871   is the inhibitory activity modulated by nsp12's association with both nsp7 and nsp8 (8).

872   However, a subsequent study reports that their own observations of IFN inhibitory

873   activity was a result of HA-tags on viral proteins in a luciferase assay (9).

874   Pro-323 is located on a bend in a loop between an alpha helix and the start of

875   a beta sheet in the interface domain. This change results in a reduction in residue size,

876   and the residue is located near the surface of the structure, where nsp8 is closely

877   associated (Fig 10). The change may have potential to affect the association of nsp8

878   with nsp12 by affecting local structure, but when taking residue variability into account

879   it seems that the protein is able to accommodate changes at this point and there are

880   no direct bonds from this residue. Moreover, this sequence variant is shared between

881   all three isolates and, thus, unlikely to account for differences between them.

882   Gly-671 is located in the RdRp domain, but does not form part of the catalytic

883   site. The replacement of gly-671 by serine does not appear to affect polar connections

884   in Pymol, although prediction in 3D-Covid increases polar connections from 3 to 5 to

885   residues in adjacent loops. Gly-671 is located on the surface of the protein, but some

886   distance from the binding sites of nsp 7, nsp8 and the RNA binding groove (Fig 11).

887

900

901 *Nsp13: Helicase.*

902 PDB structure 7re2.

903

904 Delta Mutation. P77L. Proline to Leucine.

905 Blosum score of -3. Special case to hydrophobic.

906 ConSurf score of 8. Highly conserved residue.

907 $\Delta\Delta G^{stability}$ mCSM: -0.5 kcal/mol^{-1} (Destabilising).

908 This mutation is present in 98.8% of all Delta sequences.

909

910 BA.2 Mutation. R392C. Arginine to Cysteine.

911 Blosum score of -3. Positively charged to special case.

912 ConSurf score of 1. Highly variable residue.

913 $\Delta\Delta G^{stability}$ mCSM: -0.3 kcal/mol^{-1} (Destabilising).

914 This mutation is present in 99.06% of all BA.2 sequences.

915

916   Nsp13 consists of five domains arranged in a triangular shape. 1A, 2A and 1B

917 form the base, which are connected via a stalk domain to the N-terminal zinc-binding

918 domain (ZBD) at the apex (Fig 12). Nsp13 has been shown in complex with the SARS-

919 CoV-2 replication complex (Nsp7, Nsp8 and Nsp12), with the implication that these

920 interactions have potential implications for helicase activity.

921

922   Pro-77 is located at a bend in a loop in the ZBD. When in a complex, the ZBD

923 has close association with the N-terminal helical extension of nsp8 (Fig13), although

924 in this PDB structure there are no bonds between the area. Given the consurf score

925 of this residue, there may be structural importance to this area of which we are

926 unaware, although the domain as a whole appears to be flexible (10).

927

928   Arg-392 is located in the 1A domain at the bottom of the triangular structure. It

929   does not form part of any helicase motifs, but in this particular PDB structure it makes

930   several polar bonds both within the surrounding beta sheets, and with a residue on

931   nearby nsp7 (Figs 14-15). This connection appears significant in terms of the overall

932   replication and transcription complex. There are not many other locations on nsp13

933   where there is close contact between these proteins. On mutation to cysteine this polar

934   bond is lost (Fig 16).
935

936   **Figure 12. Nsp 13.** Cartoon representation of Nsp 13. The Zinc binding domain is

960

961   Nsp13 interacts with TBK1, disrupting its association with MAVS. The Pro-77

962   mutation has been modelled in a molecular docking study to investigate how this might

963   affect the binding of nsp13 with TBK1, with the conclusion that Pro-77 may result in

964   greater affinity between nsp13 and TBK1, possibly enhancing inhibitory effects (Fig

965   17) (11).

966

967
Figure 17. Key residues of Nsp13 thought to mediate association with TBK1.

969   Cartoon representation of nsp13 in which key residues are coloured deep blue, at the

970   top of the protein. Although pro-77 is located a little distance from these residues, it is

971   on the same plane and the P77L mutation is predicted to enhance inhibitory action.

975   PDB structure 7n0c.

976

977   BA.1/BA.2 Mutation. I42V. Isoleucine to Valine.

978   Blosum score of 3. Both hydrophobic.

979   ConSurf score of 5. Middle of range.

980   $\Delta\Delta G^{stability}$ mCSM: -1.06 kcal/mol^{-1} (Destabilising).

981   This mutation is present in 95% of all BA.1 sequences and 97.6% of all BA.2

982   sequences.

983

984   Nsp14 contains a C-terminal domain, which carries S-adenosyl methionine

985   (SAM)-dependent N7-MTase activity and plays a role in viral RNA 5' capping,

986   facilitating viral mRNA stability and translation and preventing detection by innate

987   antiviral responses.

988   It also contains an N-terminal ExoN domain (3' to 5' exoribonuclease activity).

989   Nsp10 (a zinc binding protein) associates with nsp14 enhancing ExoN but not N7-

990   MTase activity, through increased structural stability.

991   Mutations that abolish the nsp14-nsp10 interaction result in a lethal phenotype

992   in SARS-CoronaVirus (i.e. the virus doesn't survive/replicate).

993

994   Overexpression of nsp14 in an *in vitro* model reduced host cell translation and

995   inhibited IFN-dependent induction of ISGs. Both domains were necessary for this

996   inhibition, and association with nsp10 enhanced the inhibitory effect (12).

997

998   Ile-42 is located in the ExoN domain, although it is distant from the active site

999   (Figs 18-19).

1000   Specifically, it is located in a long flexible region which mediates association

1001   with nsp10 (Figs 20-21).
1002

1003   **Figure 18. Nsp14 in association with Nsp10.** Cartoon representation of nsp14 (light

1004   blue chain). The ExoN domain is on the left side of the image, N7-MTase is on the

1017

1018
1019

1020 **Figure 21. Nsp14 ExoN domain in association with Nsp10.** Residues reported to

1021 be key to the interaction between Nsp10 and Nsp14 are Lys-43 and His-80 of Nsp10

1022   (highlighted in orange above). There is no association between these residues and

1023   Ile-42. Source PDB structure 7n0c.

1024

1025   Running this mutation through mCSM-PPI2 shows that there is a very small

1026   increase in affinity (0.059 kcal/mol) predicted in terms of Ile-42 and surrounding

1027   residues in nsp14. This residue already makes multiple hydrophobic connections with

1028   surrounding residues, so this part of the protein appears structurally stable. There are

1029   no bonds with nsp10 involved. Therefore, this mutation appears to be of minimal

1030   consequence.

1031

1032   *Nsp15: EndoU/Endoribonuclease*

1033   PDB structure 7tqv

1034

1035   BA.2 Mutation. T113I. Threonine to Isoleucine.

1036   Blosum score of -1. Polar uncharged to hydrophobic.

1037   ConSurf score of 7. Moderately conserved.

1038 $\Delta\Delta G^{stability}$ mCSM: -0.054 kcal/mol^{-1} (Destabilising).

1039   This mutation is present in 96% of all BA.2 sequences.

1040

1041   Structures in PDB are commonly arranged as a hexamer, a dimer of nsp15

1042   trimers. There are three domains - an N terminal domain important for oligomerization,

1043   a variable middle domain, and an endonuclease domain. Nsp15 preferentially cleaves

1044   RNA substrates 3' of uridines. It may regulate the length of polyuridines found at the

1045   5' end of negative strand viral RNA to evade activation of host innate immune

1046   responses (13)

1047

1048   Thr-113 is located in the variable middle domain. This part of the protein is not

1049   involved in nuclease activity or oligomerization. Thr-113 does not form any polar bonds

1050   with other residues in this chain or other chains within the proposed hexamer

1051   arrangement and this does not change upon mutation to Ile-113. The mutation

1052   therefore appears unlikely to have a substantial impact..
1053

1054   **Figure 22. Cartoon of Nsp15.** Cartoon representation of Nsp15 with viral RNA in

1055   association. Thr-113 is highlighted in red.

1056

1057   **ORF3a**

1058   PDB structure 7kjr.

1059

1060   Delta Mutation. S26L. Serine to Leucine.

1061   Blosum score of -2. Polar uncharged to hydrophobic.

1062   ConSurf score of 1. Highly variable.

1063 $\Delta\Delta G^{stability}$ mCSM: -0.27 kcal/mol^{-1} (Destabilising).

1064   This mutation is present in 99.2% of all Delta sequences.

1065

1066   BA.2 Mutation. T223I. Threonine to Isoleucine.

1067   Blosum score of -1. Polar uncharged to hydrophobic.

1068   ConSurf score of 9. Highly conserved.

1069 $\Delta\Delta G^{stability}$ mCSM: -0.23 kcal/mol^{-1} (Destabilising).

1070   This mutation is present in 99.3% of all BA.2 sequences.

1071

1072   As a transmembrane protein, ORF3a has two domains, a tall transmembrane

1073   domain and a cytosolic domain. The cytosolic domain is mainly composed of beta

1074   sheets, and the BA.2 mutation is located at the bottom edge of the last of these.

1075   According to modelling in Pymol the mutation appears to reduce the number of polar

1076   bonds this residue forms with neighbouring residues in the beta-sheet from 3 to 1,

1077   although somewhat contradicting this the 3-D Covid site predicts an increase in

1078   hydrophobic connections and hydrogen bonds on mutation. Thr-223 is not close to an

1079   ion channel, but could potentially cause some disruption to dimer formation since it is

1080   located at a point of interaction between the two chains (Fig 24).

1081

1082   Ser-26 is located at the C-terminal and is not included in any PDB structures to

1083   date. It appears to be a highly variable region where mutation will be of little

1084   consequence.

1085

1086   ORF3a is thought to upregulate SOCS1, a negative regulator of cytokine

1087   signalling, and through this action, inhibit JAK/STAT signalling. A series of

1088   experiments using truncated versions of ORF3a showed that the residues essential to

1089   IFN inhibitory activity are 70-130, which form two of the three alpha-helices. None of

1090   the mutations listed above fall within this range (14).

1091

1111

1112 Structure from AlphaFold.

1113 AlphaFold model shows transmembrane protein structure similar to protein 3a,

1114 there is a tall transmembrane domain composed of alpha-helices with a shorter

1115 cytosolic domain composed of beta sheets.

1116

1117 BA.1/BA.2 Mutation. Q19E. Glutamine to Glutamic acid.

1118 Blosum score of 2. Uncharged to negative charge.

1119 ConSurf score of 6. Moderately conserved.

1120 $\Delta\Delta G^{stability}$ mCSM: -0.81 kcal/mol^{-1} (Destabilising).

1121 This mutation is present in 96.0% of all BA.1 and 95.3% of all BA.2 sequences.

1122

1123 BA.1/BA.2 Mutation. A63T. Alanine to Threonine.

1124 Blosum score of 0. Hydrophobic to polar uncharged.

1125 ConSurf score of 7. Moderately conserved.

1126 $\Delta\Delta G^{stability}$ mCSM: -1.42 kcal/mol^{-1} (Destabilising).

1127 This mutation is present in 97.2% of all BA.1 and 98.5% of all BA.2 sequences.

1128

1129 Delta Mutation. I82T. Isoleucine to Threonine.

1130 Blosum score of -1. Hydrophobic to polar uncharged.

1131 ConSurf score of 8. Highly conserved.

1132 $\Delta\Delta G^{stability}$ mCSM: -2.9 kcal/mol^{-1} (Destabilising).

1133 This mutation is present in 98.9% of all Delta sequences.

1134

1135   All of these mutations are located within the transmembrane domain, each on

1136   separate alpha-helices. They are all located towards the top of the domain, each

1137   corresponding with a transmembrane motif. The transmembrane domain is thought to

1138   interact with RIG-1, ultimately inhibiting production of type I and type III IFN production

1139   induced by RIG-I/MDA5 (15).

1140

1141   From Pymol modelling, Iso-82 increases polar bonds from 3 to 4 on mutation,

1142   whereas Glu-19 and Ala 63 decrease theirs, from 3 to 2 and 4 to 2 respectively. 3-D

1143   Covid predictions are largely in concordance with this except the prediction for Iso-82

1144   is a large reduction in stability due to loss of hydrophobic connections and the

1145   introduction of several clashes. Overall this suggests that all three mutations might

1146   decrease stability in these motif areas. So, despite blosum scores indicating that these

1147   are mutations of low impact, their positioning may lead them to having greater
1148   significance.

1149
1150

1163 **ORF6**

1164 PDB structure 7vph.

1165

1166 BA.2 Mutation. D61L. Aspartic acid to Leucine.

1167 Blosum score of -4. Negatively charged to hydrophobic.

1168 ConSurf score of 9. Highly conserved.

1169 $\Delta\Delta G^{stability}$ mCSM: 0.73 kcal/mol^{-1} (Stabilising).

1170 This mutation is present in 97.6% of all BA.2 sequences.

1171

1172   There is only one model of this structure in PDB covering the C-terminal

1173 (residues 53-61), and here it is shown with a ribonucleic acid export 1 (Rae1)–

1174 nucleoporin 98 (Nup98) complex. It is thought that ORF6 antagonises host interferon

1175 signalling through association with this complex, tight binding competitively inhibits

1176 binding of host RNA and subsequent export (16,17)

1177

1178   This change has the potential to be significant. The C-terminal of Orf6 binds to

1179 the RNA binding pocket of the Rae1-Nup98 complex. There are polar bonds along the

1180 length of this C-terminal domain, but the area of greatest binding is with Asp-61, which

1181 forms 5 polar bonds with 3 residues on Rae1 (Fig 28). In contrast Leucine retains just
1182 1 bond with one of the residues (Fig 30).

1183

1205   PPI2 predicts two hydrogen bonds in addition to the polar bond shown above

1206   connecting Leu-61 to Thr-256, and a total reduction in affinity between these proteins

1207   by -1.031 kcal/mol. Source PDB structure 7vph.

1208

1209 **ORF7a**

1210

1211 PDB structure 7ci3.

1212

1213 Delta Mutation. V82A. Valine to Alanine.

1214 Blosum score of 0. Both hydrophobic.

1215 ConSurf score of 1. Highly variable.

1216 $\Delta\Delta G^{stability}$ mCSM: -0.5 kcal/mol^{-1} (Destabilising).

1217 This mutation is present in 93.3% of all Delta sequences.

1218

1219   This PDB structure shows the Ig-like ectodomain of the transmembrane protein

1220 7a. This domain is bracketed by an N-terminal signalling region and a hydrophobic

1221 transmembrane domain containing a short ER retention motif, but no models are

1222 available of these domains.

1223

1224   Val-82 is located on a loop extended from a sequence of beta sheets, before

1225 connecting to the transmembrane domain. ORF7a is thought to block STAT2

1226 phosphorylation, although details on which domains are implicated in this are currently

1227 unclear (18). The Ig-like ectodomain of ORF7a may directly interact with monocytes

1228 and modulate their antigen presenting ability (19). Key residues within this domain are

1229 located on and around the beta sheets, and Val-82 falls outside of this area. Its

1230 mutation does not alter the polar bonding it has with Arg-80. 3-D Covid predicts

1231 hydrophobic associations with Leu-88 (not shown in this model), also unaffected upon

1232 mutation. Therefore, this mutation appears to be of little significance.
1233

1234 **Figure 31. The Ig-like ectodomain of ORF7a.** Cartoon representation of the Ig-like

1235 ectodomain of ORF7a. Val-82 is highlighted in green. Source PDB structure 7ci3.

1236

1237 **Nucleocapsid protein**

1238 *N-terminal binding domain.*

1239 PDB structure 7act.

1240

1241 Delta Mutation. D63G. Aspartic acid to Glycine.

1242 Blosum score of -1. Negative charge to special case.

1243 ConSurf score of 1. Highly variable.

1244 $\Delta\Delta G^{stability}$ mCSM: 0.44 kcal/mol^{-1} (Stabilising).

1245 This mutation is present in 96.9% of all Delta sequences.

1246

1247 There are 8 other mutated residues in Supplementary Table 1, but none of the

1248 existing models cover these residues.

1249

1250 Asp-63 is located on a loop, seemingly away from main structural elements of

1251 this part of the protein, yet a proposed RNA binding groove lies in this domain over a

1252 nearby loop and Asp-63 is positioned at one end of this groove. The N-terminal domain

1253 has also been shown to be sufficient to suppress the activation of ISRE promoter, and

1254 reduce levels of p-STAT1 (20). There is a large reduction in residue size with this

1255 mutation, and there is potential for a change in the stability of RNA binding, but

1256 ConSurf results suggest residue variability at this site is common suggesting that the

1257 impact of this mutation may be minimal.

1269

1270

1271   **Spike Protein**

1272   PDB Structures 6vxx and 7fg3.

1273

1274   S assembles as a homotrimer when acting as transmembrane proteins on

1275   virions. Two subunits S1 and S2 are separated by a cleavage site S1/S2. S1 contains

1276   a receptor binding domain which mediates ACE2 binding, whilst S2 contains segments

1277   that mediate fusion with host cell membranes. S^2 represents a second cleavage site

1278   with S2.

1279

1280   The S1 region of S protein is highly variable, being most exposed to neutralising

1281   antibodies, and S as a whole is subject to intense research scrutiny. Consequently,

1282   there are over 800 structures available on PDB. 6vxx was selected to model mutations

1283   of interest as this cryo-EM structure was determined from S protein expression

1284   generated using the reference strain sequence. 7fg3 was also selected as it contained

1285   one of the most complete structures available.

1286

1287   S protein may influence host innate interferon responses. Cell fusion and

1288   syncytia formation appears to induce activation of cyclic GMP-AMP synthase (cGAS),

1289   and its downstream effector (STING), stimulating expression of IFN-beta. The S2'

1290   cleavage site appears to be essential to syncytia formation, with S1/S2 cleavage site

1291   enhancing this activity but not being essential to it. Removal of S2' sequence results

1292   in absence of cGAS-STING pathway activation (21)**.**

1293   However, there are no mutations located in or around the S2' region in any of

1294   our isolates.

1295

1296   *S1/S2 cleavage site*

1297

1298   BA.1/BA.2 Mutation. N679K: Asparagine to Lysine.

1299   Blosum score of -1. Uncharged to positively charged.

1300   ConSurf score of 2. Highly variable.

1301 $\Delta\Delta G^{stability}$ mCSM: 0.04 kcal/mol^{-1} (Neutral).

1302   This mutation is present in 98.5% of all BA.1 and 99.8% of all BA.2 sequences.

1303

1304   BA.1/BA.2 Mutation. P681H: Proline to Histidine.

1305   Blosum score of -2. Special case to positively charged.

1306   ConSurf score of 1. Highly variable.

1307 $\Delta\Delta G^{stability}$ mCSM: -0.34 kcal/mol^{-1} (Destabilising).

1308   This mutation is present in 98.0% of all BA.1 and 99.5% of all BA.2 sequences.

1309

1310   Delta Mutation. P681R: Proline to Arginine.

1311   Blosum score of -2. Special case to positively charged.

1312   ConSurf score of 1. Highly variable.

1313 $\Delta\Delta G^{stability}$ mCSM: 0.06 kcal/mol^{-1} (Neutral).

1314   This mutation is present in 99.1% of all Delta sequences.

1315

1316   Whilst these residues do not appear to have much impact on structural stability

1317   they lie on a surface-exposed loop and P681 forms part of a furin motif ($_{681}$PRRXR$_{685}$)
1318   that can be processed by multiple proteases including TMPRSS2. There are reports

1319   that both P681H and P681R can lead to increased cleavage efficiency at S1/S2,

1320   possibly by providing greater accessibility to proteases, which results in increased

1321   fusion and syncytia formation (22–25).

1322

1323 **Figure 35. The S1/S2 cleavage site of S Protein.** Close view of the S1/S2 cleavage

1325 681 and Asn-679 are highlighted in red. Source PDB structure 7fg3.

1326
1327 **Figure 36. The S1/S2 cleavage site of S Protein.** Close view of the S1/S2 cleavage

1328 site of S protein, represented as spheres. Asn-679 and Pro-681 are highlighted in red.

1329 Source PDB structure 7fg3.

1330   S protein may interact directly with the JAK1-STAT1 pathway. There is some

1331   evidence that the S1 subunit interacts directly with STAT1, inhibiting ISRE promoter

1332   activation (26). There is no information available as of yet, as to the structural basis of

1333   this interaction with STAT1, or if it involves the NTD or RBD of S1, therefore we have

1334   considered both domains.

1335

1336   *S1-NTD*

1337

1338   BA.2 Mutation. L24S, always followed by Del25/27, sometimes recorded as

1339   A27S. The whole sequence of residues has a ConSurf score of 1. Highly variable.

1340   These mutations are present in 94.5% of all BA.2 sequences.

1341

1342   BA.1 Mutation. A67V. Alanine to Valine.

1343   Blosum score of 0. Both hydrophobic.

1344   ConSurf score of 1. Highly variable.

1345 $\Delta\Delta G^{stability}$ mCSM: -0.09 kcal/mol^{-1} (Neutral).

1346   This mutation is present in 95.8% of BA.1 sequences.

1347

1348   BA.1 Mutation. Del 69/70.

1349   ConSurf scores of 1. Highly variable.

1350   These deletions are present in 94.5% of all BA.1 sequences.

1351

1352   BA.1/Delta Mutation. T95I. Threonine to Isoleucine.

1353   Blosum score of -1. Polar uncharged to hydrophobic.

1354   ConSurf score of 4. Moderately variable.

1355 $\Delta\Delta G^{stability}$ mCSM: -0.41 kcal/mol^{-1} (Destabilising).

1356   This mutation is present in 37.9% of all Delta and 93.1% of all BA.1 sequences.

1357

1358   Delta/BA.1/BA.2 Mutation. G142D. Glycine to Aspartic Acid.

1359   Blosum score of -1. Special case to negatively charged.

1360   ConSurf score of 1. Highly variable.

1361 $\Delta\Delta G^{stability}$ mCSM: -0.71 kcal/mol^{-1} (Destabilising).

1362   This mutation is present in 66% of all Delta, 93.2% of all BA.1 and 97.9% of all BA.2

1363   sequences.

1364

1365   BA.1 Mutation. Del 143/145.

1366   ConSurf scores of 1 and 2. Highly variable.

1367   These deletions are present in 93% of all BA.1 sequences.

1368

1369   BA.1 Mutation N211I. Asparagine to Isoleucine, typically followed by Del212.

1370   Consurf scores of 1. Highly variable.

1371   These mutations are present in 84.7% and 85.3% of all BA.1 sequences.

1372

1373   BA.2 Mutation. V213G. Valine to Glycine.

1374   Blosum score of -3. Hydrophobic to special case.

1375   ConSurf score of 1. Highly variable.

1376 $\Delta\Delta G^{stability}$ mCSM: -0.57 kcal/mol^{-1} (Destabilising).

1377   This mutation is present in 99.0% of all BA.2 sequences.

1378

1379   Delta Mutation. A222V. Alanine to Valine.

1380   Blosum score of 0. Both hydrophobic.

1381   ConSurf score of 1. Highly variable.

1382 $\Delta\Delta G^{stability}$ mCSM: 0.26 kcal/mol^{-1} (Stabilising).

1383   This mutation is only present in 10% of all Delta sequences.

1384

1385   The majority of these mutations occur on surface loops of the NTD within

1386   regions observed to be highly variable, presumably due to exposure to neutralising

1387   antibodies. There are also several deletion sequences, again located on loops which

1388   appear to be able to accommodate these changes. The one exception to this trend is

1389   the BA.1/Delta mutation T95I, which is part of a beta sheet strand, deeper within the

1390   domain. The destabilising effect of this mutation appears to be the result of clashes

1391   formed with surrounding residues.

1392   However, our limited knowledge of STAT1 interactions with S1 makes it hard

1393   to draw firm conclusions on the significance of any of these mutations.
1394

1398

1399 *S1-RBD*

1400

1401 BA.1/BA.2 Mutation. G339D. Glycine to Aspartic Acid.

1402 Blosum score of -1. Special case to negatively charged.

1403 ConSurf score of 1. Highly variable.

1404 $\Delta\Delta G^{stability}$ mCSM: -0.49 kcal/mol^{-1} (Destabilising).

1405 This mutation is present in 91.0% of all BA.1 and 97.1% of all BA.2 sequences.

1406

1407 BA.1 Mutation. S371L. Serine to Leucine.

1408 Blosum score of -2. Polar uncharged to hydrophobic.

1409 ConSurf score of 7. Moderately conserved.

1410 $\Delta\Delta G^{stability}$ mCSM: -0.21 kcal/mol^{-1} (Destabilising).

1411 This mutation is present in 82.2% of all BA.1 sequences.

1412

1413 BA.1 Mutation. S371F. Serine to Phenylalanine.

1414 Blosum score of -2. Polar uncharged to hydrophobic.

1415 ConSurf score of 7. Moderately conserved.

1416 $\Delta\Delta G^{stability}$ mCSM: -1.00 kcal/mol^{-1} (Destabilising).

1417 This mutation is present in 95.3% of all BA.2 sequences.

1418

1419 BA.1/BA.2 Mutation. S373P. Serine to Proline.

1420   Blosum score of -1. Polar uncharged to special case.

1421   ConSurf score of 4. Moderately variable.

1422 $\Delta\Delta G^{stability}$ mCSM: -0.34 kcal/mol^{-1} (Destabilising).

1423   This mutation is present in 83.1% of all BA.1 and 97.2% of all BA.2 sequences.

1424

1425   BA.1/BA.2 Mutation. S375F. Serine to Phenylalanine.

1426   Blosum score of -2. Polar uncharged to hydrophobic.

1427   ConSurf score of 8. Highly conserved.

1428 $\Delta\Delta G^{stability}$ mCSM: -0.89 kcal/mol^{-1} (Destabilising).

1429   This mutation is present in 82.9% of all BA.1 and 97.1% of all BA.2 sequences.

1430

1431   BA.2 Mutation. D405N. Aspartic Acid to Asparagine.

1432   Blosum Score of 1. Negatively charged to polar uncharged.

1433   ConSurf score of 2. Highly variable.

1434 $\Delta\Delta G^{stability}$ mCSM: -0.82 kcal/mol^{-1} (Destabilising).

1435   This mutation is present in 97.8% of all BA.2 sequences.

1436

1437   BA.2 Mutation. R408S. Arginine to Serine.

1438   Blosum score of -1. Positively charged to polar uncharged.

1439   ConSurf score of 6. Moderately conserved.

1440 $\Delta\Delta G^{stability}$ mCSM: -0.08 kcal/mol^{-1} (Destabilising).

1441   This mutation is present in 93.6% of all BA.2 sequences.

1442

1443   BA.2 (and BA.1?) Mutation. K417N. Lysine to Asparagine.

1444   Blosum score of -1. Positively charged to polar uncharged.

1445   ConSurf score of 9. Highly conserved.

1446 $\Delta\Delta G^{stability}$ mCSM: 0.47 kcal/mol^{-1} (Destabilising).

1447   This mutation is present in 94.5% of all BA.2 sequences (and 61.9% of all BA.1

1448   sequences - unconfirmed if present in our BA.1 isolate).

1449

1450   BA.2 Mutation. N440K: Asparagine to Lysine.

1451   Blosum score of -1. Polar uncharged to positively charged.

1452   ConSurf score of 1. Highly variable.

1453 $\Delta\Delta G^{stability}$ mCSM: 0.22 kcal/mol^{-1} (Stabilising).

1454   This mutation is present in 87.3% of all BA.2 sequences (and 63.7% of all BA.1

1455   sequences - unconfirmed if present in our BA.1 sequence).

1456

1457   Delta Mutation. L452R. Leucine to Arginine.

1458   Blosum score of -2. Hydrophobic to positively charged.

1459   ConSurf score of 1. Highly variable.

1460 $\Delta\Delta G^{stability}$ mCSM: -0.92 kcal/mol^{-1} (Destabilising).

1461   This mutation is present in 96.8% of all Delta sequences.

1462

1463   BA.1/BA.2 Mutation. Q493R. Glutamine to Arginine.

1464   Blosum score of 0. Polar uncharged to positively charged.

1465   Consurf score of 1. Highly variable.

1466 $\Delta\Delta G^{stability}$ mCSM: -0.34 kcal/mol^{-1} (Destabilising).

1467   This mutation is present in 84.3% of all BA.1 and 93.9% of all BA.2 sequences.

1468

1469   BA.1 Mutation. G496S. Glycine to Serine.

1470   Blosum score of 0. Special case to polar uncharged.

1471   Consurf score of 1. Highly variable.

1472 $\Delta\Delta G^{stability}$ mCSM: -0.59 kcal/mol^{-1} (Destabilising).

1473   This mutation is present in 80.6% of all BA.1 sequences.

1474

1475   BA.1/BA.2 Mutation. Q498R. Glutamine to Arginine.

1476   Blosum score of 0. Polar uncharged to positively charged.

1477   Consurf score of 1. Highly variable.

1478 $\Delta\Delta G^{stability}$ mCSM: 0.17 kcal/mol^{-1} (Stabilising).

1479   This mutation is present in 80.3% of all BA.1 and 92.4% of all BA.2 sequences.

1480

1481   BA.1/BA.2 Mutation. N501Y. Asparagine to Tyrosine. Bonding changes are significant.

1482   Blosum score of -3. Polar uncharged to hydrophobic.

1483   Consurf score of 1. Highly variable.

1484 $\Delta\Delta G^{stability}$ mCSM: -0.37 kcal/mol^{-1} (Destabilising).

1485   This mutation is present in 80.9% of all BA.1 and 92.6% of all BA.2 sequences.

1486

1487   BA.1/BA.2 Mutation. Y505H. Tyrosine to Histidine.

1488   Blosum score of 2. Hydrophobic to positively charged.

1489   Consurf score of 1. Highly variable.

1490 $\Delta\Delta G^{stability}$ mCSM: -0.61 kcal/mol^{-1} (Destabilising).

1491   This mutation is present in 81.3% of all BA.1 and 92.3% of all BA.2 sequences.

1492

1493   BA.1 Mutation. T547K. Threonine to Lysine.

1494   Blosum score of -1. Polar uncharged to positively charged.

1495   Consurf score of 4. Moderately variable.

1496 $\Delta\Delta G^{stability}$ mCSM: -0.51 kcal/mol^{-1} (Destabilising).

1497   This mutation is present in 98.2% of all BA.1 sequences.

1498

1499   Delta/BA.1/BA.2 Mutation. D614G. Aspartic Acid to Glycine.

1500   Blosum score of -1. Negatively charged to special case.

1501   Consurf score of 5. Middle of range.

1502 $\Delta\Delta G^{stability}$ mCSM: -0.28 kcal/mol^{-1} (Destabilising).

1503   This mutation is present in 99.3% of all Delta, 98.8% of all BA.1, and 99.9% of all BA.2

1504   sequences.

1505

1506   BA.1/BA.2 Mutation. H655Y. Histidine to Tyrosine.

1507   Blosum score of 2. Positively charged to hydrophobic.

1508   Consurf score of 6. Moderately conserved.

1509 $\Delta\Delta G^{stability}$ mCSM: 1.21 kcal/mol^{-1} (Stabilising).

1510   This mutation is present in 98.5% of all BA.1, and 99.9% of all BA.2 sequences.

1511

1512   The majority of the mutations in the S1 subunit RBD are located on surface

1513   loops of the receptor binding motif (437-508), several of which have been noted as

1514   mutations of interest (L452R, S477N, N501Y) due to their modulation of binding affinity

1515   between S-protein and ACE-2 receptors, whilst K417N appears to reduce the

1516   neutralising capacity of sera (27). As with the NTD of S-protein there is no information

1517   about any specific interactions with STAT1 available to inform the structure models

1518   here.
Figure 38. The Receptor Binding Domain of S-protein. Cartoon representation of the RBD of S-protein. BA.2 mutations are highlighted in red, BA.1 in orange, and Delta in green. Source PDB structure 6xvv.
